The internuclear distance given by multiplying Eq. (13.546) by two is:

$$2c'=2.08418a_0=1.10290\ X\ 10^{-10}\ m \tag{13.547}$$

The experimental bond distance is [38]:

$$2c'=1.079\ X\ 10^{-10}\ m \tag{13.548}$$

Substitution of Eqs. (13.545-13.546) into Eq. (13.62) gives:

$$b=c=1.25198a_0=6.62518\ X\ 10^{-11}\ m \tag{13.549}$$

Substitution of Eqs. (13.545-13.546) into Eq. (13.63) gives:

$$e=0.63974 \tag{13.550}$$

The nucleus of the H atom and the nucleus of the C atom comprise the foci of each H_2-type ellipsoidal MO. The parameters of the point of intersection of each H_2-type ellipsoidal MO and the $C2sp^3$ HO are given by Eqs. (13.84-13.95), (13.261-13.270), and (13.434-13.442). The polar intersection angle θ' is given by Eq. (13.261) where $r_n = r_{2sp^3} = 0.91771a_0$ is the radius of the $C2sp^3$ shell. Substitution of Eqs. (13.545-13.546) into Eq. (13.261) gives:

$$\theta' = 85.65° \tag{13.551}$$

Then, the angle θ_{C2sp^3HO} the radial vector of the $C2sp^3$ HO makes with the internuclear axis is:

$$\theta_{C2sp^3HO} = 180° - 85.65° = 94.35° \tag{13.552}$$

as shown in Figure 13.9. The parametric angle θ_{H_2MO} given by Eqs. (13.442-13.443), (13.549), and (13.552) is:

$$\theta_{H_2MO} = 46.96° \tag{13.553}$$

Then, the distance d_{H_2MO} along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals given by Eqs. (13.445), (13.545), and (13.553) is:

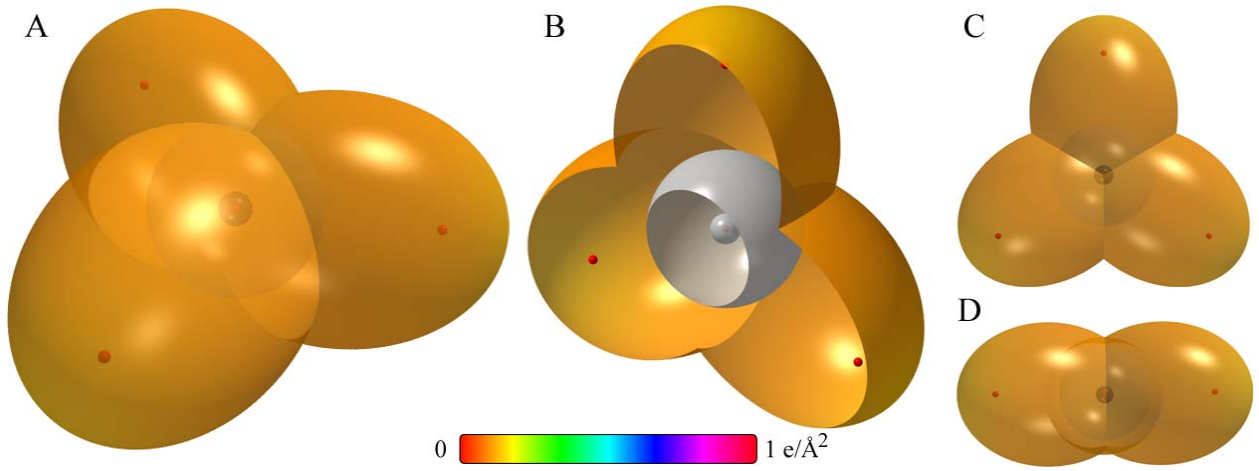
$$\begin{aligned} d_{H_2MO} &= 1.11172a_0 \\ &= 5.88295\ X\ 10^{-11}\ m \end{aligned} \tag{13.554}$$

The distance d_{C2sp^3HO} along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals given by Eqs. (13.447), (13.546), and (13.554) is:

$$d_{C2sp^3HO} = 0.06963a_0 = 3.68457\ X\ 10^{-12}\ m \tag{13.555}$$

As shown in Eq. (13.540), the uniform charge-density in the $C2sp^3$ HO is increased by a factor of 0.25 and the H-atom density is decreased by a factor of 0.25 for each $C-H$ bond. Using the orbital composition of CH_3 (Eq. (13.540)), the radii of $C1s = 0.17113a_0$ (Eq. (10.51)) and $C2sp^3 = 0.91771a_0$ (Eq. (13.424)) shells, and the parameters of the CH_3 MO given by Eqs. (13.3-13.4), (13.545-13.547), and (13.549-13.555), the charge-density of the CH_3 MO comprising the linear combination of three $C-H$-bond MOs is shown in Figure 13.12. Each $C-H$-bond MO comprises a H_2-type ellipsoidal MO and a $C2sp^3$ HO having the dimensional diagram shown in Figure 13.9.

Figure 13.12. CH_3 MO comprising the linear combination of three $C-H$-bond MOs. Each $C-H$-bond MO comprises the superposition of a H_2-type ellipsoidal MO and a $C2sp^3$ HO with a relative charge-density of 0.75 to 1.25; otherwise, the $C2sp^3$ HO shell is unchanged. (A) Color scale, translucent view of the charge-density of the CH_3 MO from the top. For each $C-H$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C2sp^3$ HO, the $C2sp^3$ HO shell, $C1s$ shell, and the nuclei (red, not to scale) are shown. (B) Cut-away view showing the inner most $C1s$ shell, and moving radially, the $C2sp^3$ shell, and the H_2-type ellipsoidal MO that transitions to the $C2sp^3$ HO for each $C-H$ bond. Bisector current not shown. (C)-(D) Color scale, bottom, top, and side-on translucent views of the charge-density of the CH_3 MO, respectively.



ENERGIES OF CH_3

The energies of CH_3 are three times those of CH and are given by the substitution of the semiprincipal axes (Eqs. (13.545-13.546) and (13.549)) into the energy equations Eq. (13.541) and (Eqs. (13.449-13.452)) that are multiplied by three:

$$V_e = 3(0.91771)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -108.94944\ eV \tag{13.556}$$

$$V_p = \frac{3e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 39.16883\ eV \tag{13.557}$$

$$T = 3(0.91771)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 33.44213\ eV \tag{13.558}$$

$$V_m = 3(0.91771)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -16.72107\ eV \tag{13.559}$$

$$E_T(CH_3) = -\frac{3e^2}{8\pi\varepsilon_0 c'}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-14.63489\ eV = -67.69444\ eV \tag{13.560}$$

where $E_T(CH_3)$ is given by Eq. (13.541) which is reiteratively matched to Eq. (13.542) within five-significant-figure-round-off-error.

VIBRATION OF CH_3

The vibrational energy levels of CH_3 may be solved as three equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [2] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

THE DOPPLER ENERGY TERMS OF $^{12}CH_3$

The reentrant oscillation of hybridized orbitals in the transition state is not coupled. Therefore, the equations of the radiation reaction force of methyl radical are the same as those of the corresponding hydrogen carbide radicals with the substitution of the methyl radical parameters. Using Eqs. (11.136) and (13.140-13.142), the angular frequency of the reentrant oscillation in the transition state is:

$$\omega = \sqrt{\frac{\frac{0.75e^2}{4\pi\varepsilon_0 b^3}}{m_e}} = 2.55577\ X\ 10^{16}\ rad/s \tag{13.561}$$

where b is given by Eq. (13.549). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)):

$$\overline{E}_K = \hbar\omega = \hbar 2.55577\ X\ 10^{16}\ rad/s = 16.82249\ eV \tag{13.562}$$

In Eq. (11.181), substitution of $E_T(H_2)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each H_2-type MO, for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (13.562) for $\overline{E}_K$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$\begin{aligned}\overline{E}_D &\cong E_{h\nu}\sqrt{\frac{2\overline{E}_K}{Mc^2}} \\ &= -31.63537\ eV\sqrt{\frac{2e(16.82249\ eV)}{m_e c^2}} = -0.25670\ eV\end{aligned} \tag{13.563}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of CH_3 due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\overline{E}_{osc}$, is given by the sum of the corresponding energies, $\overline{E}_D$ given by Eq. (13.563) and $\overline{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of each $C-H$ bond. Using ω_e given by Eq. (13.458) for $\overline{E}_{Kvib}$ of the transition state having three independent bonds, $\overline{E}'_{osc}(^{12}CH_3)$ per bond is

$$\overline{E}'_{osc}(^{12}CH_3) = \overline{E}_D + \overline{E}_{Kvib} = \overline{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{13.564}$$

$$\bar{E}'_{osc}\left({}^{12}CH_3\right) = -0.25670\ eV + \frac{1}{2}\left(0.35532\ eV\right) = -0.07904\ eV \tag{13.565}$$

Given that the vibration and reentrant oscillation is for three $C-H$ bonds, $\bar{E}_{osc}\left({}^{12}CH_3\right)$, is:

$$\begin{aligned}\bar{E}_{osc}\left({}^{12}CH_3\right) &= 3\left(\bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)\\ &= 3\left(-0.25670\ eV + \frac{1}{2}\left(0.35532\ eV\right)\right) = -0.23711\ eV\end{aligned} \tag{13.566}$$

TOTAL AND BOND ENERGIES OF ${}^{12}CH_3$

$E_{T+osc}\left({}^{12}CH_3\right)$, the total energy of the ${}^{12}CH_3$ radical including the Doppler term, is given by the sum of $E_T\left(CH_3\right)$ (Eq. (13.543)) and $\bar{E}_{osc}\left({}^{12}CH_3\right)$ given by Eq. (13.566).

$$E_{T+osc}\left(CH_3\right) = V_e + T + V_m + V_p + E\left(C,2sp^3\right) + \bar{E}_{osc}\left({}^{12}CH_3\right) = E_T\left(CH_3\right) + \bar{E}_{osc}\left({}^{12}CH_3\right) \tag{13.567}$$

$$\begin{aligned}E_{T+osc}\left({}^{12}CH_3\right) &= \left\{\begin{array}{l}\left(\frac{-3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-14.63489\ eV\right)\\ -3\left(\left(31.63536831\ eV\right)\sqrt{\frac{2\hbar\sqrt{\frac{3}{4}\frac{e^2}{4\pi\varepsilon_0 b^3}}}{m_e c^2}}-\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)\end{array}\right\}\\ &= -67.69450\ eV - 3\left(0.25670\ eV - \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)\end{aligned} \tag{13.568}$$

From Eqs. (13.564-13.568), the total energy of ${}^{12}CH_3$ is:

$$\begin{aligned}E_{T+osc}\left({}^{12}CH_3\right) &= -67.69450\ eV + \bar{E}_{osc}\left({}^{12}CH_3\right)\\ &= -67.69450\ eV - 3\left(0.25670\ eV - \frac{1}{2}\left(0.35532\ eV\right)\right)\\ &= -67.93160\ eV\end{aligned} \tag{13.569}$$

where ω_e given by Eq. (13.458) was used for the $\hbar\sqrt{\frac{k}{\mu}}$ term.

The CH_3 bond dissociation energy, $E_D\left({}^{12}CH_3\right)$, is given by the sum of the total energies of the CH_2 radical and the hydrogen atom minus $E_{T+osc}\left({}^{12}CH_3\right)$:

$$E_D\left({}^{12}CH_3\right) = E\left({}^{12}CH_2\right) + E(H) - E_{T+osc}\left({}^{12}CH_3\right) \tag{13.570}$$

where $E_T({}^{12}CH_2)$ is given by the sum of the energies of the $C2sp^3$ HO, $E\left(C,2sp^3\right)$ given by Eq. (13.428), $2E_D(H)$ given by Eq. (13.154), and the negative of the bond energies of ${}^{12}CH$ given by Eq. (13.489) and ${}^{12}CH_2$ given by Eq. (13.528):

$$\begin{aligned}E({}^{12}CH_2) &= 2\left(-13.59844\ eV\right) - 14.63489\ eV - 3.47\ eV - 4.33064\ eV\\ &= -49.63241\ eV\end{aligned} \tag{13.571}$$

Thus, the ${}^{12}CH_3$ bond dissociation energy, $E_D\left({}^{12}CH_3\right)$, given by Eqs. (13.154), and (13.569-13.571) is:

$$\begin{aligned}E_D\left({}^{12}CH_3\right) &= +\left(-49.63241\ \ eV - 13.59844\ eV\right) - E_{T+osc}\left({}^{12}CH_3\right)\\ &= -63.23085eV - \left(-67.93160\ eV\right)\\ &= 4.70075\ eV\end{aligned} \tag{13.572}$$

The experimental ${}^{12}CH_3$ bond dissociation energy is [40]

$$E_D\left({}^{12}CH_3\right) = 4.72444\ eV \tag{13.573}$$

BOND ANGLE OF $^{12}CH_3$

Consider the case that all of the MOs can participate in a superposition involving bonding of the terminal atoms. Then, solving for $2c'_{H-H} = 3.61109a_0$, the distance between any adjacent two H atoms when the total energy of the corresponding MO is zero given by Eq. (13.531) with the replacement of the hybridization factor and energy terms with $(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)$ of Eq. (13.568), and $2c'_{C-H}$, the internuclear distance of each $C-H$ bond (Eq. (13.547)), the corresponding bond angle can be determined from the law of cosines. Using Eq. (13.537), the bond angle θ between the $C-H$ bonds is:

$$\theta = \cos^{-1}\left(\frac{2(2.08418)^2-(3.61109)^2}{2(2.08418)^2}\right) = \cos^{-1}(-0.50099) = 120° \tag{13.574}$$

which is in agreement with D_{3h} symmetry [38].

The CH_3 radical has a pyramidal structure with the carbon atom along the z-axis at the apex and the hydrogen atoms at the base in the xy-plane. The distance $d_{origin-H}$ from the origin to the nucleus of a hydrogen atom given by Eqs. (13.534) and (13.412) is:

$$d_{origin-H} = 2.0848a_0 \tag{13.575}$$

The height along the z-axis of the pyramid from the origin to the C nucleus is d_{height} given by Eqs. (13.414), (13.547), and (13.575) is:

$$d_{height} = 0a_0 \tag{13.576}$$

The angle θ_v of each $C-H$ bond from the z-axis given by Eqs. (13.416), (13.575), and (13.576) is:

$$\theta_v = 90° \tag{13.577}$$

The CH_3 MO shown in Figure 13.12 was rendered using these parameters.

The results of the determination of bond parameters of CH_3 are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

METHANE MOLECULE (CH_4)

The methane molecule CH_4 is formed by the reaction of a hydrogen atom with a methyl radical:

$$CH_3 + H \rightarrow CH_4 \tag{13.578}$$

CH_4 can be solved using the same principles as those used to solve and CH_3 wherein the carbon $2s$ and $2p$ shells hybridize to form a single $2sp^3$ shell as an energy minimum. Four diatomic molecular orbitals (MOs) developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section serve as basis functions in a linear combination with four carbon $2sp^3$ hybridized orbitals (HOs) to form the MO of CH_4. The solution is very similar to that of CH_3 except that there are four CH bonds in CH_4. Methane is the simplest hydrocarbon that can be solved using the results for CH_3. From the solution of CH_2 as well as CH_3, more complex hydrocarbons can be solved using these radicals as basis elements with bonding between the $C2sp^3$ hybridized carbons.

FORCE BALANCE OF CH_4

CH_4 comprises four chemical bonds between carbon and hydrogen atoms. Each $C-H$ bond comprises two spin-paired electrons with one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom. Each H-atom electron forms a H_2-type ellipsoidal MO with an unpaired C-atom electrons. However, such a bond is not possible with the outer two C electrons in their ground state since the resulting H_2-type ellipsoidal MO would have a shorter internuclear distance than the radius of the carbon $2p$ shell which is not energetically stable, and only two electrons are unpaired. Thus, when bonding the carbon $2s$ and $2p$ shells hybridize to form a single $2sp^3$ shell as an energy minimum. The electron configuration and the energy, $E\left(C,2sp^3\right)$, of the $C2sp^3$ shell is given by Eqs. (13.422), and (13.428), respectively.

For each $C-H$ bond, a $C2sp^3$ electron combines with the $H1s$ electron to form a molecular orbital. The proton of the H atom and the nucleus of the C atom are along each internuclear axis and serve as the foci. As in the case of H_2, each of the four $C-H$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into the $C2sp^3$ HO for distances shorter than the radius of the $C2sp^3$ shell since it is energetically unfavorable. Thus, each MO surface comprises a prolate spheroid at the H proton that can be solved as being continuous with the $C2sp^3$ shell at the C atom whose nucleus

serves as the other focus. The radius and the energy of the $C2sp^3$ shell are unchanged with bond formation. The central paramagnetic force due to spin of each $C-H$ bond is provided by the spin-pairing force of the CH_4 MO that has the symmetry of an s orbital that superimposes with the $C2sp^3$ orbitals such that the corresponding angular momenta are unchanged.

The energies in the CH_4 MO involve only each $C2sp^3$ and each $H1s$ electron with the formation of each $C-H$ bond. The sum of the energies of the H_2-type ellipsoidal MOs is matched to that of the $C2sp^3$ shell. As in the cases of OH, H_2O, NH, NH_2, NH_3, CH, CH_2, and CH_3 the CH_4 MO must comprise four $C-H$ bonds with each having 75% of a H_2-type ellipsoidal MO and a $C2sp^3$ HO in a linear combination in order to match potential, kinetic, and orbital energy relationships:

$$4\left[1\,C2sp^3+0.75\,H_2\;MO\right]\rightarrow CH_4\;MO \tag{13.579}$$

The force balance of the CH_4 MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.579) and the energy matching condition between the hydrogen and $C2sp^3$ HO components of the MO.

The force constant k' to determine the ellipsoidal parameter c' of the each H_2-type-ellipsoidal-MO component of the CH_4 MO in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus c' is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $C-H$-bond MO. Since each of the four prolate spheroidal $C-H$-bond MOs comprises a H_2-type-ellipsoidal MO that transitions to the $C2sp^3$ HO, the energy $E\left(C,2sp^3\right)$ in Eq. (13.428) adds to that of the four corresponding H_2-type ellipsoidal MOs to give the total energy of the CH_4 MO. From the energy equation and the relationship between the axes, the dimensions of the CH_4 MO are solved.

The energy components of V_e, V_p, T, and V_m are four times those of CH corresponding to the four $C-H$ bonds. Since each prolate spheroidal H_2-type MO transitions to the $C2sp^3$ HO and the energy of the $C2sp^3$ shell must remain constant and equal to the $E\left(C,2sp^3\right)$ given by Eq. (13.428), the total energy $E_T\left(CH_4\right)$ of the CH_4 MO is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $C2sp^3$ HO and the four H_2-type ellipsoidal MOs that forms the CH_4 MO as given by Eq. (13.579). Using Eq. (13.431), $E_T\left(CH_4\right)$ is given by:

$$E_T\left(CH_4\right)=E_T+E\left(C,2sp^3\right)=-\frac{4e^2}{8\pi\varepsilon_0 c'}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-14.63489\;eV \tag{13.580}$$

The four hydrogen atoms and the hybridized carbon atom can achieve an energy minimum as a linear combination of four H_2-type ellipsoidal MOs each having the proton and the carbon nucleus as the foci. Hybridization gives rise to the $C2sp^3$ HO-shell Coulombic energy $E_{Coulomb}\left(C,2sp^3\right)$ given by Eq. (13.435). To meet the equipotential condition of the union of the H_2-type-ellipsoidal-MO and the $C2sp^3$ HO, the electron energies in Eqs. (13.431), (13.495), (13.541), and (13.580) were normalized by the ratio of $14.82575\;eV$, the magnitude of $E_{Coulomb}\left(C,2sp^3\right)$ given by Eq. (13.425), and $13.605804\;eV$, the magnitude of the Coulombic energy between the electron and proton of H given by Eq. (1.264). The factor given by Eq. (13.430) normalized the energies to match that of the Coulombic energy alone to meet the energy matching condition of each $C-H$-bond MO under the influence of the proton and the C nucleus. Each $C-H$-bond MO comprises the same $C2sp^3$ shell having its energy normalized to that of the Coulombic energy between the electron and a charge of $+e$ at the carbon focus of the CH_4 MO. Thus, the energy of the CH_4 MO is also given by the sum of that of the four H_2-type ellipsoidal MOs given by Eq. (11.212) minus three times the Coulombic energy, $E_{Coulomb}\left(H\right)=-13.605804\;eV$, of the three redundant $+e$'s of the linear combination:

$$\begin{aligned}E_T\left(4H_2-3H\right)&=-\frac{4e^2}{8\pi\varepsilon_0 a_0}\left[\left(2\sqrt{2}-\sqrt{2}+\frac{\sqrt{2}}{2}\right)\ln\frac{\sqrt{2}+1}{\sqrt{2}-1}-\sqrt{2}\right]-3E_{Coulomb}\left(H\right)\\&=4\left(-31.63536831\;eV\right)-3\left(-13.605804\;eV\right)\\&=-85.72406\;eV\end{aligned} \tag{13.581}$$

$E_T\left(CH_4\right)$ given by Eq. (13.580) is set equal to four times the energy of the H_2-type ellipsoidal MO minus three times the Coulombic energy of H given by Eq. (13.581):

$$E_T\left(CH_4\right)=-\frac{4e^2}{8\pi\varepsilon_0 c'}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-14.63489\;eV=-85.72406\;eV \tag{13.582}$$

From the energy relationship given by Eq. (13.582) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the CH_4 MO can be solved.

Substitution of Eq. (13.60) into Eq. (13.543) gives:

$$\frac{4e^2}{8\pi\varepsilon_0\sqrt{\frac{2aa_0}{3}}}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{2aa_0}{3}}}{a-\sqrt{\frac{2aa_0}{3}}}-1\right]=e71.08917 \tag{13.583}$$

The most convenient way to solve Eq. (13.583) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is

$$a=1.62340a_0=8.59066\ X\ 10^{-11}\ m \tag{13.584}$$

Substitution of Eq. (13.584) into Eq. (13.60) gives:

$$c'=1.04032a_0=5.50514\ X\ 10^{-11}\ m \tag{13.585}$$

The internuclear distance given by multiplying Eq. (13.585) by two is:

$$2c'=2.08064a_0=1.10103\ X\ 10^{-10}\ m \tag{13.586}$$

The experimental bond distance is [41] :

$$2c'=1.087\ X\ 10^{-10}\ m \tag{13.587}$$

Substitution of Eqs. (13.584-13.585) into Eq. (13.62) gives:

$$b=c=1.24626a_0=6.59492\ X\ 10^{-11}\ m \tag{13.588}$$

Substitution of Eqs. (13.584-13.585) into Eq. (13.63) gives:

$$e=0.64083 \tag{13.589}$$

The nucleus of the H atom and the nucleus of the C atom comprise the foci of each H_2-type ellipsoidal MO. The parameters of the point of intersection of each H_2-type ellipsoidal MO and the $C2sp^3$ HO in the absence of the other three are given by Eqs. (13.84-13.95), (13.261-13.270), (13.434-13.442), and (13.551-13.555). The polar intersection angle θ' is given by Eq. (13.261) where $r_n=r_{2sp^3}=0.91771a_0$ is the radius of the $C2sp^3$ shell. Substitution of Eqs. (13.584-13.585) into Eq. (13.261) gives:

$$\theta'=86.20° \tag{13.590}$$

Then, the angle θ_{C2sp^3HO} the radial vector of the $C2sp^3$ HO makes with the internuclear axis is:

$$\theta_{C2sp^3HO}=180°-86.20°=93.80° \tag{13.591}$$

as shown in Figure 13.9. The parametric angle θ_{H_2MO} given by Eqs. (13.442-13.443), (13.588), and (13.591) is:

$$\theta_{H_2MO}=47.29° \tag{13.592}$$

Then, the distance d_{H_2MO} along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals given by Eqs. (13.445), (13.584), and (13.592) is:

$$d_{H_2MO}=1.10121a_0=5.82734\ X\ 10^{-11}\ m \tag{13.593}$$

The distance d_{C2sp^3HO} along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals given by Eqs. (13.447), (13.585), and (13.593) is:

$$d_{C2sp^3HO}=0.06089a_0=3.22208\ X\ 10^{-12}\ m \tag{13.594}$$

The H_2-type ellipsoidal MOs do not actually directly contact the $C2sp^3$ HO. As discussed in the Force Balance of H_2O section, with the addition of the fourth $C-H$ bond, the H_2-type ellipsoidal MOs may linearly combine to form a continuous two-dimensional surface of equipotential equivalent to that of the MOs if they did contact the $C2sp^3$ HO. However, Eqs. (13.579-13.580) must hold based on conservation of momentum and the potential, kinetic, and total energy relationships. In order that there is current continuity given the constraints of Eqs. (13.579-13.580), the existence of a self-contained, continuous-current, linear-combination of the H_2-type ellipsoidal MOs requires that electrons are divisible between the combination H_2-type MO and the $C2sp^3$ HO. This is not possible.

Thus, at the points of intersection of the H_2-type MOs of methane symmetry, and in similar geometries such as that of CH_3, representative of the general case, electron indivisibility, current continuity, and conservation of energy and angular momentum require that the current between the $C2sp^3$ shell and points of mutual contact is projected onto and flows along the radial vector to the surface of $C2sp^3$ shell. This current designated the bisector current (BC) meets the $C2sp^3$ surface and does not travel to distances shorter than its radius.

Moreover, an energy minimum is obtained when the H-atom charge-density of each $C-H$-bond MO is decreased by a factor of 0.25 with a corresponding 0.25 increase in that of the three other $C-H$-bond MOs. In this case, the angular momentum components of the transferred current mutually cancel. The geometry of the equivalent bonds is tetrahedral. The symmetry point group is T_d. This geometry is equivalent to the indistinguishable bonds positioned uniformly on a spherical surface or also at the apexes of a cube. The predicted angle θ between the $C-H$ bonds is:

$$\theta = 109.5° \tag{13.595}$$

The experimental bond angle is [41]:

$$\theta = 109.5° \tag{13.596}$$

The polar angle ϕ at which the H_2-type ellipsoidal MOs intersect is given by the bisector of the angle θ between the $C-H$ bonds:

$$\phi = \frac{109.5}{2} = 54.75° \tag{13.597}$$

With the carbon nucleus defined as the origin and one of the $C-H$ bonds defined as the positive x-axis, the polar-coordinate angle of the intersection occurs at:

$$\phi' = 54.75° + 180° = 234.75° \tag{13.598}$$

The polar radius r_i at this angle is given by Eqs. (13.84-13.85):

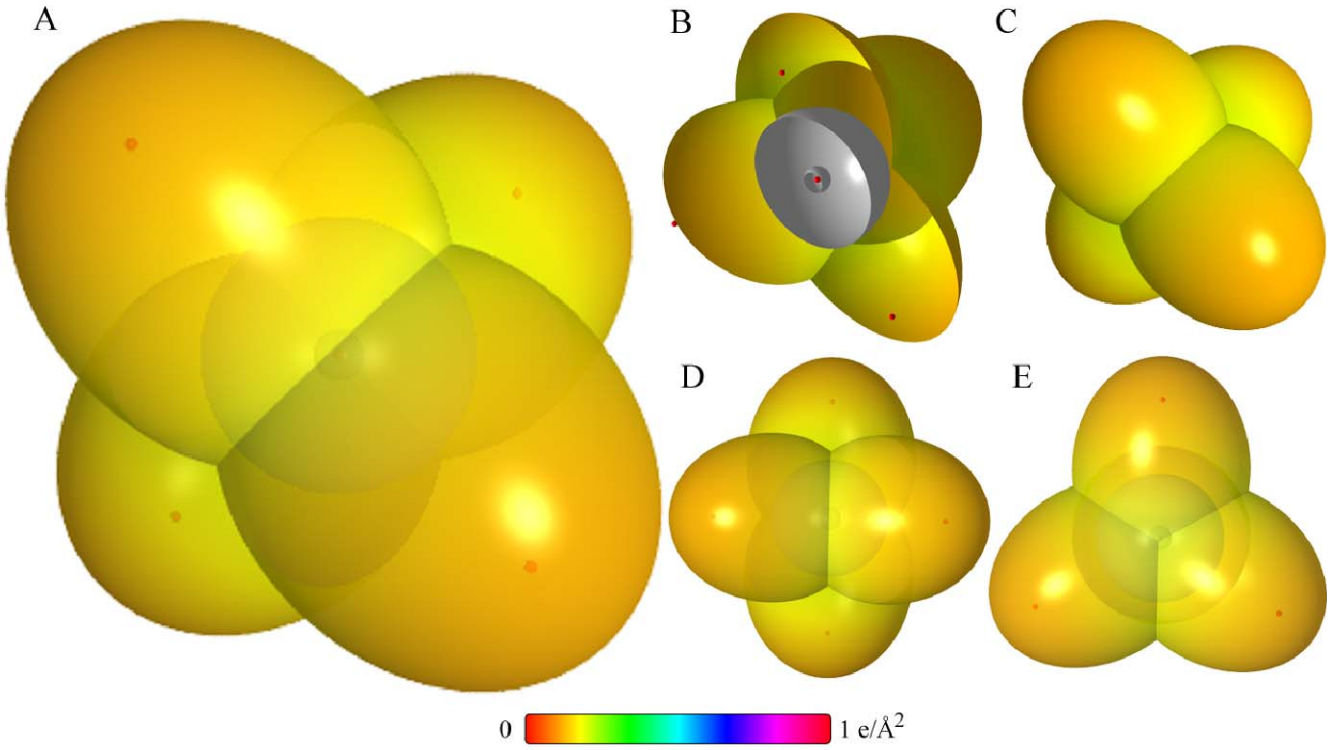
$$r_i = (a - c')\frac{1 + \frac{c'}{a}}{1 + \frac{c'}{a}\cos\phi'} \tag{13.599}$$

Substitution of Eqs. (13.584-13.585) and (13.589) into Eq. (13.599) gives:

$$r_i = 1.52223a_0 = 8.05530\ X\ 10^{-11}\ m \tag{13.600}$$

Using the orbital composition of CH_4 (Eq. (13.579)), the radii of $C1s = 0.17113a_0$ (Eq. (10.51)) and $C2sp^3 = 0.91771a_0$ (Eq. (13.424)) shells, and the parameters of the CH_4 MO given by Eqs. (13.3-13.4), (13.584-13.586), and (13.588-13.600), the charge-density of the CH_4 MO comprising the linear combination of four $C-H$-bond MOs is shown in Figure 13.13. Each $C-H$-bond MO having the dimensional diagram shown in Figure 13.9 comprises a H_2-type ellipsoidal MO and a $C2sp^3$ HO according to Eq. (13.579). But, based on the T_d symmetry of the H_2-type MOs, the charge is distributed 1:1 between the H_2-type MOs and the $C2sp^3$ shell.

Figure 13.13. CH_4 MO comprising the linear combination of four $C-H$ -bond MOs formed by the superposition of a H_2-type ellipsoidal MO and a $C2sp^3$ HO. (A) Color scale, translucent view of the charge-density of the CH_4 MO. The combined surface of the four H_2-type ellipsoidal MOs from each $C-H$ bond that surrounds the $C2sp^3$ HO, the $C2sp^3$ HO shell, $C1s$ shell, and the nuclei (red, not to scale) are shown. (B) Off-center cut-away view showing the complete inner most $C1s$ shell, and moving radially, the $C2sp^3$ shell, and the H_2-type ellipsoidal MOs that surround the $C2sp^3$ HO. Bisector current not shown. (C) Opaque view. (D)-(E) Additional translucent views.



ENERGIES OF CH_4

The energies of CH_4 are four times those of CH and are given by the substitution of the semiprincipal axes (Eqs. (13.584-13.585) and (13.588)) into the energy equations Eq. (13.580) and (Eqs. (13.449-13.452)) that are multiplied by four:

$$V_e = 4(0.91771)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -145.86691\ eV \tag{13.601}$$

$$V_p = \frac{4e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 52.31390\ eV \tag{13.602}$$

$$T = 4(0.91771)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 44.92637\ eV \tag{13.603}$$

$$V_m = 4(0.91771)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -22.46318\ eV \tag{13.604}$$

$$\begin{aligned} E_T(CH_4) &= -\frac{4e^2}{8\pi\varepsilon_0 c'}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-14.63489\ eV \\ &= -85.72472\ eV \end{aligned} \tag{13.605}$$

where $E_T(CH_4)$ is given by Eq. (13.580) which is reiteratively matched to Eq. (13.581) within five-significant-figure round-off error.

VIBRATION OF CH_4

The vibrational energy levels of CH_4 may be solved as four equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [2] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

THE DOPPLER ENERGY TERMS OF $^{12}CH_4$

The reentrant oscillation of hybridized orbitals in the transition state is not coupled. Therefore, the equations of the radiation reaction force of methane are the same as those of OH, CH, CH_2, and CH_3 with the substitution of the methane parameters. Using Eqs. (11.136) and (13.140-13.142), the angular frequency of the reentrant oscillation in the transition state is:

$$\omega = \sqrt{\frac{0.75e^2}{4\pi\varepsilon_0 b^3}} = 2.57338\ X\ 10^{16}\ rad/s \tag{13.606}$$

where b is given by Eq. (13.588). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K = \hbar\omega = \hbar 2.57338\ X\ 10^{16}\ rad/s = 16.93841\ eV \tag{13.607}$$

In Eq. (11.181), substitution of $E_T\left(H_2\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each H_2-type MO, for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (13.607) for $\bar{E}_K$ gives the Doppler energy of the electrons of each of the four bonds for the reentrant orbit:

$$\begin{aligned}\bar{E}_D &\cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}} \\ &= -31.63537\ eV\sqrt{\frac{2e(16.93841\ eV)}{m_e c^2}} = -0.25758\ eV\end{aligned} \tag{13.608}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of CH_4 due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (13.608) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of each $C-H$ bond. Using ω_e given by Eq. (13.458) for $\bar{E}_{Kvib}$ of the transition state having four independent bonds, $\bar{E}'_{osc}\left(^{12}CH_4\right)$ per bond is:

$$\bar{E}'_{osc}\left(^{12}CH_4\right) = \bar{E}_D + \bar{E}_{Kvib} = \bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{13.609}$$

$$\bar{E}'_{osc}\left(^{12}CH_4\right) = -0.25758\ eV + \frac{1}{2}(0.35532\ eV) = -0.07992\ eV \tag{13.610}$$

The reentrant orbit for the binding of a hydrogen atom to a CH_3 radical involves four $C-H$ bonds. Since the vibration and reentrant oscillation is along four bonds, $\bar{E}_{osc}$ for $^{12}CH_4$, $\bar{E}_{osc}\left(^{12}CH_4\right)$, is:

$$\begin{aligned}\bar{E}_{osc}\left(^{12}CH_4\right) &= 4\left(\bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \\ &= 4\left(-0.25758\ eV + \frac{1}{2}(0.35532\ eV)\right) = -0.31967\ eV\end{aligned} \tag{13.611}$$

TOTAL AND BOND ENERGIES OF $^{12}CH_4$

$E_{T+osc}\left(^{12}CH_4\right)$, the total energy of the $^{12}CH_4$ radical including the Doppler term, is given by the sum of $E_T\left(CH_4\right)$ (Eq. (13.582)) and $\bar{E}_{osc}\left(^{12}CH_4\right)$ given by Eq. (13.611).

$$E_{T+osc}\left(CH_4\right)=V_e+T+V_m+V_p+E\left(C,2sp^3\right)+\bar{E}_{osc}\left(^{12}CH_4\right)=E_T\left(CH_4\right)+\bar{E}_{osc}\left(^{12}CH_4\right) \tag{13.612}$$

$$\begin{aligned}E_{T+osc}\left(^{12}CH_4\right)&=\left\{\begin{array}{l}\left(\dfrac{-4e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+c'}{a-c'}-1\right]-14.63489\ eV\right)\\ -4\left(\left(31.63536831\ eV\right)\sqrt{\dfrac{2\hbar\sqrt{\dfrac{\frac{3}{4}\dfrac{e^2}{4\pi\varepsilon_0 b^3}}{m_e}}}{m_e c^2}}-\dfrac{1}{2}\hbar\sqrt{\dfrac{k}{\mu}}\right)\end{array}\right\}\\ &=-85.72406\ eV-4\left(0.25758\ eV-\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)\end{aligned} \tag{13.613}$$

From Eqs. (13.609-13.613), the total energy of $^{12}CH_4$ is:

$$\begin{aligned}E_{T+osc}\left(^{12}CH_4\right)&=-85.72406\ eV+\bar{E}_{osc}\left(^{12}CH_4\right)\\ &=-85.72406\ eV-4\left(0.25758\ eV-\frac{1}{2}\left(0.35532\ eV\right)\right)=-86.04373\ eV\end{aligned} \tag{13.614}$$

where ω_e given by Eq. (13.458) was used for the $\hbar\sqrt{\dfrac{k}{\mu}}$ term.

The CH_4 bond dissociation energy, $E_D\left(^{12}CH_4\right)$, is given by the sum of the total energies of the CH_3 radical and the hydrogen atom minus $E_{T+osc}\left(^{12}CH_4\right)$:

$$E_D\left(^{12}CH_4\right)=E\left(^{12}CH_3\right)+E(H)-E_{T+osc}\left(^{12}CH_4\right) \tag{13.615}$$

where $E_T(^{12}CH_3)$ is given by the sum of the energies of the $C2sp^3$ HO, $E\left(C,2sp^3\right)$ given by Eq. (13.428), $3E_D\left(H\right)$ given by Eq. (13.154), and the negative of the bond energies of ^{12}CH given by Eq. (13.489), $^{12}CH_2$ given by Eq. (13.528), and $^{12}CH_3$ given by Eq. (13.573):

$$E(^{12}CH_3)=\begin{pmatrix}3\left(-13.59844\ eV\right)-14.63489\ eV\\ -3.47\ eV-4.33064\ eV-4.72444\ eV\end{pmatrix}=-67.95529\ eV \tag{13.616}$$

Thus, the $^{12}CH_4$ bond dissociation energy, $E_D\left(^{12}CH_4\right)$, given by Eqs. (13.154), and (13.614-13.616) is:

$$\begin{aligned}E_D\left(^{12}CH_4\right)&=-\left(67.95529\ \ eV+13.59844\ eV\right)-E_{T+osc}\left(^{12}CH_4\right)\\ &=-81.55373\ eV-\left(-86.04373\ eV\right)=4.4900\ eV\end{aligned} \tag{13.617}$$

The experimental $^{12}CH_4$ bond dissociation energy is [40] :

$$E_D\left(^{12}CH_4\right)=4.48464\ eV \tag{13.618}$$

The results of the determination of bond parameters of CH_4 are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

NITROGEN MOLECULE

The nitrogen molecule can be formed by the reaction of two nitrogen atoms:

$$N + N \rightarrow N_2 \tag{13.619}$$

The bond in the nitrogen molecule comprises a H_2-type molecular orbital (MO) with two paired electrons. The force balance equation and radius r_7 of the $2p$ shell of N is derived in the Seven-Electron Atoms section. With the formation of the H_2-type MO by the contribution of a $2p$ electron from each N atom, a diamagnetic force arises between the remaining $2p$ electrons and the H_2-type MO. This force from each N causes the H_2-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the integer increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining $2p$ electrons of each N decrease the radius of the corresponding shell such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of N_2 is $1s_1^2 1s_2^2 2s_1^2 2s_2^2 2p_1^2 2p_2^2 \sigma_{1,2}^2$ where the subscript designates the N atom, 1 or 2, σ designates the H_2-type MO, and the orbital arrangement is:

σ state

$\uparrow\downarrow$

2p state

$\uparrow\downarrow$	$\uparrow\downarrow$
0	0

2s state

$\uparrow\downarrow$	$\uparrow\downarrow$

1s state

$\uparrow\downarrow$	$\uparrow\downarrow$
$N1$	$N2$

(13.620)

Nitrogen is predicted to be diamagnetic in agreement with observations.

FORCE BALANCE OF THE $2p$ SHELL OF THE NITROGEN ATOMS OF THE NITROGEN MOLECULE

For each N atom, force balance for the outermost $2p$ electron of N_2 (electron 6) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 6 and the other $2p$-shell as well as the $2s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Seven-Electron Atoms section. The central Coulomb force on the outer-most $2p$ shell electron of N_2 (electron 6) due to the nucleus and the inner five electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele} = \frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2}\mathbf{i}_\mathbf{r} \tag{13.621}$$

for $r > r_5$. The $2p$ shell possess an external electric field given by Eq. (10.92) for $r > r_6$. The energy is minimized with conservation of angular momentum. This condition is met when the diamagnetic force, $\mathbf{F}_{diamagnetic}$, of Eq. (10.82) due to the p-orbital contribution is the same as that of the reactant nitrogen atoms given by Eq. (10.136) with r_6 replacing r_7:

$$\begin{aligned}\mathbf{F}_{diamagnetic} &= -\left(\frac{1}{3}\right)\frac{\hbar^2}{4m_e r_6^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \\ &= -\frac{\hbar^2}{12m_e r_6^2 r_3}\sqrt{\frac{3}{4}}\mathbf{i}_\mathbf{r}\end{aligned} \tag{13.622}$$

And, $\mathbf{F}_{mag\ 2}$ corresponding to the conserved orbital angular momentum of the three orbitals is given by Eq. (10.89).

$$\mathbf{F}_{mag\ 2} = \frac{1}{Z}\frac{3\hbar^2}{m_e r_6^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.623}$$

The electric field external to the $2p$ shell given by Eq. (10.92) for $r > r_6$ gives rise to a second diamagnetic force,

$\mathbf{F}_{diamagnetic\ 2}$, given by Eq. (10.93). $\mathbf{F}_{diamagnetic\ 2}$ due to the binding of the p-orbital electron having an electric field of +1 outside of its radius is:

$$\mathbf{F}_{diamagnetic\ 2} = -\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{m_e r_6^4}10\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.624}$$

In addition, the contribution of a $2p$ electron from each N atom in the formation of the σ MO gives rise to a paramagnetic force on the remaining two $2p$ electrons that pair. The force, $\mathbf{F}_{mag\ 3}$, follows from Eq. (10.11) wherein the two radii are equal to r_6 and the direction is positive, central:

$$\mathbf{F}_{mag\ 3} = \frac{\hbar^2}{4m_e r_6^3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.625}$$

$\mathbf{F}_{mag\ 3}$ is present in additional diatomic molecules where its contribution minimizes the energy. This AO spin-pairing force reduces the radius directly to reduce the energy, and it can also cancel the contribution of the corresponding electron to $\mathbf{F}_{diamagnetic}$ to further reduce the energy.

The radius of the $2p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.621)) and diamagnetic (Eqs. (13.622) and (13.624)), and paramagnetic (Eqs. (13.623) and (13.625)) forces as follows:

$$\frac{m_e v_6^2}{r_6} = \left(\begin{array}{l}\dfrac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2} - \dfrac{\hbar^2}{12m_e r_6^2 r_3}\sqrt{s(s+1)} + \dfrac{3\hbar^2}{Zm_e r_6^2 r_3}\sqrt{s(s+1)} \\ -\left[\dfrac{Z-6}{Z-5}\right]\left(1-\dfrac{\sqrt{2}}{2}\right)\dfrac{r_3\hbar^2}{r_6^4 m_e}10\sqrt{s(s+1)} + \dfrac{\hbar^2}{4m_e r_6^3}\sqrt{s(s+1)}\end{array}\right) \tag{13.626}$$

Substitution of $v_6 = \dfrac{\hbar}{m_e r_6}$ (Eq. (1.35)) and $s = \dfrac{1}{2}$ into Eq. (13.626) gives:

$$\frac{\hbar^2}{m_e r_6^3} - \frac{\hbar^2}{4m_e r_6^3}\sqrt{\frac{3}{4}} = \frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2} - \frac{\hbar^2}{12m_e r_6^2 r_3}\sqrt{\frac{3}{4}} + \frac{3\hbar^2}{Zm_e r_6^2 r_3}\sqrt{\frac{3}{4}} - \left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_6^4 m_e}10\sqrt{\frac{3}{4}} \tag{13.627}$$

The quadratic equation corresponding to Eq. (13.627) is:

$$r_6^2 - \frac{\dfrac{\hbar^2}{m_e}\left(1-\dfrac{\sqrt{3}}{8}\right)}{\left(\dfrac{(Z-5)e^2}{4\pi\varepsilon_0} - \left(\dfrac{1}{12}-\dfrac{3}{Z}\right)\dfrac{\hbar^2}{m_e r_3}\sqrt{\dfrac{3}{4}}\right)}r_6 - \frac{\dfrac{\hbar^2}{m_e}\left[\dfrac{Z-6}{Z-5}\right]\left(1-\dfrac{\sqrt{2}}{2}\right)r_3 10\sqrt{\dfrac{3}{4}}}{\left(\dfrac{(Z-5)e^2}{4\pi\varepsilon_0} - \left(\dfrac{1}{12}-\dfrac{3}{Z}\right)\dfrac{\hbar^2}{m_e r_3}\sqrt{\dfrac{3}{4}}\right)} = 0 \tag{13.628}$$

The solution of Eq. (13.628) using the quadratic formula is:

$$r_6 = \frac{\dfrac{a_0\left(1-\dfrac{\sqrt{3}}{8}\right)}{\left(\dfrac{(Z-5)-\left(\dfrac{1}{12}-\dfrac{3}{Z}\right)\dfrac{\sqrt{3}}{2r_3}}\right)} \pm a_0\sqrt{\left(\dfrac{\dfrac{1-\dfrac{\sqrt{3}}{8}}{\left(\dfrac{(Z-5)-\left(\dfrac{1}{12}-\dfrac{3}{Z}\right)\dfrac{\sqrt{3}}{2r_3}}\right)}\right)^2 + \dfrac{20\sqrt{3}\left(\left[\dfrac{Z-6}{Z-5}\right]\left(1-\dfrac{\sqrt{2}}{2}\right)r_3\right)}{\left(\dfrac{(Z-5)-\left(\dfrac{1}{12}-\dfrac{3}{Z}\right)\dfrac{\sqrt{3}}{2r_3}}\right)}}}{2}, \; r_3 \text{ in units of } a_0 \tag{13.629}$$

The positive root of Eq. (13.629) must be taken in order that $r_6 > 0$. Substitution of $\dfrac{r_3}{a_0} = 0.69385$ (Eq. (10.62) with $Z = 7$) into Eq. (13.629) gives:

$$r_6 = 0.78402a_0 \tag{13.630}$$

ENERGIES OF THE $2p$ SHELL OF THE NITROGEN ATOMS OF THE NITROGEN MOLECULE

The central forces on the $2p$ shell of each N are increased with the formation of the σ MO, which reduces the shell's radius and increases its total energy. The Coulombic energy terms of the total energy of the two N atoms at the new radius are calculated and added to the energy of the σ MO to give the total energy of N_2. Then, the bond energy is determined from the total N_2 energy.

The radius r_7 of each nitrogen atom before bonding is given by Eq. (10.142).

$$r_7 = 0.93084a_0 \tag{13.631}$$

Using the initial radius r_7 of each N atom and the final radius r_6 of the $N2p$ shell of N_2 (Eq. (13.630)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_T\left(N_2,2p\right)$ of the Coulombic energy change of the $N2p$ electrons of both atoms is determined using Eq. (10.102).

$$E_T\left(N_2,2p\right) = -2\sum_{n=4}^{5}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_6}-\frac{1}{r_7}\right) = -2\left(13.60580\ eV\right)\left(0.20118\right)\left(2+3\right) = -27.37174\ eV \tag{13.632}$$

FORCE BALANCE OF THE σ MO OF THE NITROGEN MOLECULE

The $2p$ shell gives rise to two diamagnetic forces on the σ MO. As given for the hydrogen molecule in the Hydrogen-Type Molecules section, the σ MO comprises two electrons, σ electron 1 and σ electron 2, that are bound at $\xi = 0$ as a equipotential prolate spheroidal MO by the central Coulombic field due to the nitrogen atoms at the foci and the spin pairing force on σ electron 2 due to σ electron 1 that initially has smaller semiprincipal axes. The spin-pairing force given in Eq. (11.200) is equal to one half the centrifugal force of the two electrons. The spin-pairing electron of the σ MO is also repelled by the remaining $2p$ electrons of each N according to Lenz law, and the force is based on the total number of these electrons n_e that interact with the binding σ-MO electron. This diamagnetic force $\mathbf{F}_{diamagneticMO1}$ is of the same form as the molecular spin-pairing force but in the opposite direction. The force follows from the derivations of Eqs. (10.219) and (11.200) which gives:

$$\mathbf{F}_{diamagneticMO1} = \frac{n_e\hbar^2}{4m_e a^2b^2}D\mathbf{i}_\xi \tag{13.633}$$

In addition, there is a relativistically corrected Lorentz force $\mathbf{F}_{diamagneticMO2}$ on the pairing electron of the σ MO that follows from Eqs. (7.15) and (11.200):

$$\mathbf{F}_{diamagneticMO2} = \frac{1}{Z}\frac{|L|\hbar}{2m_e a^2b^2}D\mathbf{i}_\xi \tag{13.634}$$

where $|L|$ is the magnitude of the angular momentum of each N atom at a focus that is the source of the diamagnetism at the σ-MO.

The force balance equation for the σ-MO of the nitrogen molecule given by Eq. (11.200) and Eqs. (13.633-13.634) with $n_e = 2$ and $|L| = \hbar$ is:

$$\frac{\hbar^2}{m_e a^2b^2}D = \frac{e^2}{8\pi\varepsilon_0 ab^2}D + \frac{\hbar^2}{2m_e a^2b^2}D - \left(1+\frac{1}{Z}\right)\frac{\hbar^2}{2m_e a^2b^2}D \tag{13.635}$$

$$\frac{\hbar^2}{m_e a^2b^2}D = \frac{e^2}{8\pi\varepsilon_0 ab^2}D - \frac{1}{Z}\frac{\hbar^2}{2m_e a^2b^2}D \tag{13.636}$$

$$\left(2+\frac{1}{Z}\right)\frac{\hbar^2}{2m_e a^2b^2}D = \frac{e^2}{8\pi\varepsilon_0 ab^2}D \tag{13.637}$$

$$a = \left(2+\frac{1}{Z}\right)a_0 \tag{13.638}$$

Substitution of $Z = 7$ into Eq. (13.638) gives:

$$a = 2.14286a_0 = 1.13395\ X\ 10^{-10}\ m \tag{13.639}$$

Substitution of Eq. (13.639) into Eq. (11.79) is:

$$c' = 1.03510a_0 = 5.47750\ X\ 10^{-11}\ m \tag{13.640}$$

The internuclear distance given by multiplying Eq. (13.640) by two is:

$$2c' = 2.07020a_0 = 1.09550\ X\ 10^{-10}\ m \tag{13.641}$$

The experimental bond distance from Ref. [28] and Ref. [43] is:

$$2c' = 1.09769\ X\ 10^{-10}\ m \tag{13.642}$$

$$2c' = 1.094\ X\ 10^{-10}\ m \tag{13.643}$$

Substitution of Eqs. (13.639-13.640) into Eq. (11.80) is:

$$b = c = 1.87628a_0 = 9.92882\ X\ 10^{-11}\ m \tag{13.644}$$

Substitution of Eqs. (13.639-13.640) into Eq. (11.67) is:

$$e = 0.48305 \tag{13.645}$$

Using the electron configuration of N_2 (Eq. (13.620)), the radii of the $N1s = 0.14605a_0$ (Eq. (10.51)), $N2s = 0.69385a_0$ (Eq. (10.62)), and $N2p = 0.78402a_0$ (Eq. (13.630)) shells and the parameters of the σ MO of N_2 given by Eqs. (13.3-13.4), (13.639-13.641), and (13.644-13.645), the dimensional diagram and charge-density of the N_2 MO are shown in Figures 13.14 and 13.15, respectively.

Despite the predictions of standard quantum mechanics that preclude the imaging of a molecular orbital, the full three-dimensional structure of the outer molecular orbital of N_2 has been recently tomographically reconstructed [44]. The charge-density surface observed is consistent with that shown in Figure 13.15. This result constitutes direct evidence that electrons are not point-particle probability waves that have no form until they are "collapsed to a point" by measurement. Rather they are physical, two-dimensional equipotential charge density surfaces.

Figure 13.14. The cross section of the N_2 MO showing the axes, σ MO (H_2-type ellipsoidal MO), with the N $1s$, $2s$, and $2p$ atomic orbitals (AOs). Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, r_6: radius of the $N2p$ shell having two paired electrons.

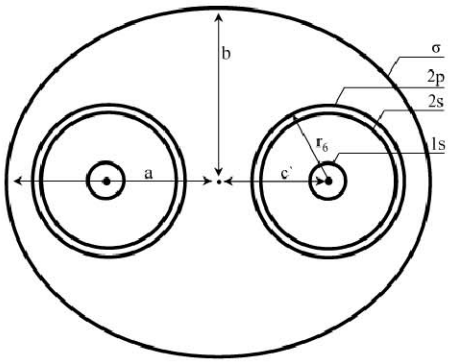


Figure 13.15. N_2 MO comprising the σ MO (H_2-type MO) with N atoms at the foci that have each donated an electron to the σ MO and have smaller radii and higher binding energies as a consequence. (A) Color scale, translucent view of the charge-density of the N_2 MO. (B) Off-center cut-away view showing the complete inner most $N1s$ shell, and moving radially, the $N2s$ shell, the $N2p$ shell, and the σ prolate spheroidal MO that have the N atoms as the foci.

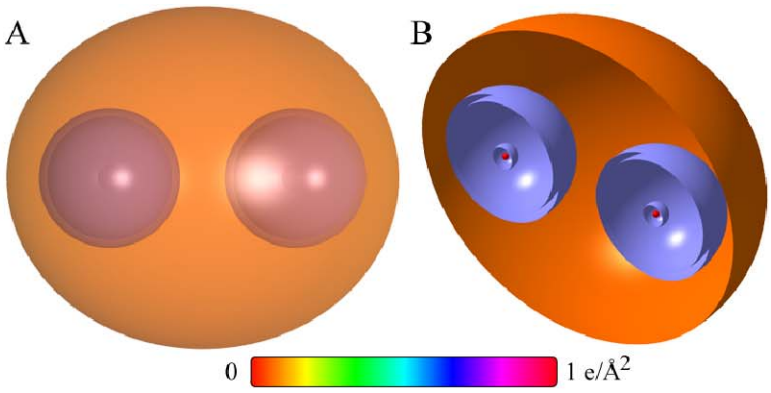

Sum of the Energies of the σ MO and the AOS of the Nitrogen Molecule

The energies of the N_2 σ MO are given by the substitution of the semiprincipal axes (Eqs. (13.639-13.640) and (13.644)) into the energy equations (Eqs. (11.207-11.212)) of H_2:

$$V_e = \frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -27.70586\ eV \tag{13.646}$$

$$V_p = \frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 13.14446\ eV \tag{13.647}$$

$$T = \frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 6.46470\ eV \tag{13.648}$$

$$V_m = \frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -3.23235\ eV \tag{13.649}$$

$$E_T = V_e + T + V_m + V_p \tag{13.650}$$

Substitution of Eqs. (11.79) and (13.646-13.649) into Eq. (13.650) gives:

$$E_T\left(N_2,\sigma\right)=\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2}}}\left(\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{2}}}{a-\sqrt{\frac{aa_0}{2}}}-1\right) \tag{13.651}$$
$$=-11.32906\ eV$$

where $E_T\left(N_2,\sigma\right)$ is the total energy of the σ MO of N_2. The sum, $E_T\left(N_2\right)$, of $E_T\left(N_2,2p\right)$, the $2p$ (AO) contribution given by Eq. (13.632), and $E_T\left(N_2,\sigma\right)$, the σ MO contribution given by Eq. (13.651) is:

$$E_T\left(N_2\right)=E_T\left(N_2,2p\right)+E_T\left(N_2,\sigma\right) \tag{13.652}$$
$$=-27.37174\ eV-11.32906\ eV=-38.70080\ eV$$

VIBRATION OF N_2

The vibrational energy levels of N_2 may be solved by determining the Morse potential curve from the energy relationships for the transition from two N atoms whose parameters are given by Eqs. (10.134-10.143) to the two N atoms whose parameter r_6 is given by Eq. (13.630) and the σ MO whose parameters are given by Eqs. (13.639-13.641) and (13.644-13.645). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K&P) [15] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

THE DOPPLER ENERGY TERMS OF THE NITROGEN MOLECULE

The equations of the radiation reaction force of nitrogen are the same as those of H_2 with the substitution of the nitrogen parameters. Using Eqs. (11.231-11.233), the angular frequency of the reentrant oscillation in the transition state is:

$$\omega=\sqrt{\frac{e^2}{4\pi\varepsilon_0 a^3 m_e}} \tag{13.653}$$
$$=1.31794\ X\ 10^{16}\ rad/s$$

where a is given by Eq. (13.639). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)):

$$\overline{E}_K=\hbar\omega \tag{13.654}$$
$$=\hbar 1.31794\ X\ 10^{16}\ rad/s=8.67490\ eV$$

In Eq. (11.181), substitution of $E_T\left(N_2\right)$ for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (13.654) for $\overline{E}_K$ gives the Doppler energy of the electrons of the reentrant orbit:

$$\overline{E}_D\cong E_{h\nu}\sqrt{\frac{2\overline{E}_K}{Mc^2}} \tag{13.655}$$
$$=-38.70080\ eV\sqrt{\frac{2e\left(8.67490\ eV\right)}{m_e c^2}}=-0.22550\ eV$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the N_2 MO due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\overline{E}_{osc}$, is given by the sum of the corresponding energies, $\overline{E}_D$ given by Eq. (13.655) and $\overline{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy. Using the experimental N_2 ω_e of 2358.57 cm^{-1} $\left(0.29243\ eV\right)$ [28] for $\overline{E}_{Kvib}$ of the transition state, $\overline{E}_{osc}\left(N_2\right)$ is:

$$\overline{E}_{osc}\left(N_2\right)=\overline{E}_D+\overline{E}_{Kvib}=\overline{E}_D+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{13.656}$$

$$\overline{E}_{osc}\left(N_2\right)=-0.22550\ eV+\frac{1}{2}\left(0.29243\ eV\right) \tag{13.657}$$
$$=-0.07929\ eV$$

TOTAL AND BOND ENERGIES OF THE NITROGEN MOLECULE

$E_{T+osc}(N_2)$, the total energy of N_2 including the Doppler term, is given by the sum of $E_T(N_2)$ (Eq. (13.652)) and $\bar{E}_{osc}(N_2)$ given by Eq. (13.657):

$$\begin{aligned} E_{T+osc}(N_2) &= V_e + T + V_m + V_p + E_T(N_2, 2p) + \bar{E}_{osc}(N_2) \\ &= E_T(N_2, \sigma) + E_T(N_2, 2p) + \bar{E}_{osc}(N_2) = E_T(N_2) + \bar{E}_{osc}(N_2) \end{aligned} \tag{13.658}$$

$$E_{T+osc}(N_2) = \left\{ \begin{array}{l} \left(\dfrac{-e^2}{8\pi\varepsilon_0 \sqrt{\dfrac{aa_0}{2}}} \left(\left(2 - \dfrac{1}{2}\dfrac{a_0}{a}\right) \ln \dfrac{a + \sqrt{\dfrac{aa_0}{2}}}{a - \sqrt{\dfrac{aa_0}{2}}} - 1 \right) - 2\sum_{n=4}^{5} \dfrac{(Z-n)e^2}{8\pi\varepsilon_0} \left(\dfrac{1}{r_6} - \dfrac{1}{r_7} \right) \right) \\ \left(1 + \sqrt{\dfrac{2\hbar \sqrt{\dfrac{e^2}{4\pi\varepsilon_0 a^3}}}{m_e c^2}} \right) + \dfrac{1}{2}\hbar\sqrt{\dfrac{k}{\mu}} \end{array} \right\} \tag{13.659}$$

$$= -38.70080\ eV - 0.22550\ eV + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}$$

From Eqs. (13.656-13.659), the total energy of the N_2 MO is:

$$\begin{aligned} E_{T+osc}(N_2) &= -38.70080\ eV + \bar{E}_{osc}(N_2) \\ &= -38.70080\ eV - 0.22550\ eV + \frac{1}{2}(0.29243\ eV) = -38.78009\ eV \end{aligned} \tag{13.660}$$

where the experimental ω_e was used for the $\hbar\sqrt{\dfrac{k}{\mu}}$ term.

The N_2 bond dissociation energy, $E_D(N_2)$, is given by the difference in the total energies of the two N atoms and $E_{T+osc}(N_2)$:

$$E_D(N_2) = 2E(N) - E_{T+osc}(N_2) \tag{13.661}$$

where the energy of a nitrogen atom is [6] :

$$E(N) = -14.53414\ eV \tag{13.662}$$

Thus, the N_2 bond dissociation energy, $E_D(N_2)$, given by Eqs. (13.660-13.662) is:

$$E_D(N_2) = -2(14.53414\ eV) - E_{T+osc}(N_2) = -29.06828\ eV - (-38.78009\ eV) = 9.71181\ eV \tag{13.663}$$

The experimental N_2 bond dissociation energy from Ref. [43] and Ref. [45] is:

$$E_D(N_2) = 9.756\ eV \tag{13.664}$$

$$E_D(N_2) = 9.764\ eV \tag{13.665}$$

The results of the determination of bond parameters of N_2 are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

OXYGEN MOLECULE

The oxygen molecule can be formed by the reaction of two oxygen atoms:

$$O + O \rightarrow O_2 \tag{13.666}$$

The bond in the oxygen molecule comprises a H_2-type molecular orbital (MO) with two paired electrons. The force balance equation and radius r_8 of the $2p$ shell of O is derived in the Eight-Electron Atoms section. With the formation of the H_2-type MO by the contribution of a $2p$ electron from each O atom, a diamagnetic force arises between the remaining $2p$ electrons and the H_2-type MO. This force from each O causes the H_2-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the integer increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining $2p$ electrons of each O decrease the radius of the corresponding shell such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of O_2 is $1s_1^2 1s_2^2 2s_1^2 2s_2^2 2p_1^3 2p_2^3 \sigma_{1,2}^2$ where the subscript designates the O atom, 1 or 2, σ designates the H_2-type MO, and the orbital arrangement is:

σ state

$\uparrow\downarrow$

2p state

$\underset{0}{\uparrow\downarrow}$ $\underset{1}{\uparrow}$ $\underset{0}{\uparrow\downarrow}$ $\underset{1}{\uparrow}$

(13.667)

2s state

$\uparrow\downarrow$ $\uparrow\downarrow$

1s state

$\underset{O1}{\uparrow\downarrow}$ $\underset{O2}{\uparrow\downarrow}$

Oxygen is predicted to be paramagnetic in agreement with observations [42].

FORCE BALANCE OF THE $2p$ SHELL OF THE OXYGEN ATOMS OF THE OXYGEN MOLECULE

For each O atom, force balance for the outermost $2p$ electron of O_2 (electron 7) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 7 and the other $2p$-shell as well as the $2s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Eight-Electron Atoms section. The central Coulomb force on the outer-most $2p$ shell electron of O_2 (electron 7) due to the nucleus and the inner six electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele} = \frac{(Z-6)e^2}{4\pi\varepsilon_0 r_7^2}\mathbf{i}_\mathbf{r} \tag{13.668}$$

for $r > r_6$. The $2p$ shell possess an external electric field given by Eq. (10.92) for $r > r_7$. The energy is minimized with conservation of angular momentum. This condition is met when the magnetic forces are the same as those of the reactant oxygen atoms with r_7 replacing r_8. The diamagnetic force, $\mathbf{F}_{diamagnetic}$, of Eq. (10.82) due to the p-orbital contributions is given by Eq. (10.156):

$$\mathbf{F}_{diamagnetic} = -\left(\frac{1}{3}+\frac{2}{3}\right)\frac{\hbar^2}{4m_e r_7^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} = -\frac{3\hbar^2}{12m_e r_7^2 r_3}\sqrt{\frac{3}{4}}\mathbf{i}_\mathbf{r} \tag{13.669}$$

And, $\mathbf{F}_{mag\ 2}$ corresponding to the conserved spin and orbital angular momentum given by Eq. (10.157) is:

$$\mathbf{F}_{mag\ 2} = \frac{1}{Z}\frac{2\hbar^2}{m_e r_7^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.670}$$

The electric field external to the $2p$ shell given by Eq. (10.92) for $r > r_7$ gives rise to a second diamagnetic force, $\mathbf{F}_{diamagnetic\ 2}$, given by Eq. (10.93). $\mathbf{F}_{diamagnetic\ 2}$ due to the binding of the p-orbital electron having an electric field of +1 outside of its radius is :

$$\mathbf{F}_{diamagnetic\ 2} = -\left[\frac{Z-7}{Z-6}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{m_e r_7^4}10\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.671}$$

The radius of the $2p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.688)) and diamagnetic (Eqs. (13.669) and (13.671)), and paramagnetic (Eq. (13.670)) forces as follows:

$$\frac{m_e v_7^2}{r_7} = \left(\begin{array}{l}\frac{(Z-6)e^2}{4\pi\varepsilon_0 r_7^2} - \frac{3\hbar^2}{12m_e r_7^2 r_3}\sqrt{s(s+1)} + \frac{2\hbar^2}{Zm_e r_7^2 r_3}\sqrt{s(s+1)} \\ -\left[\frac{Z-7}{Z-6}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_7^4 m_e}10\sqrt{s(s+1)}\end{array}\right) \tag{13.672}$$

Substitution of $v_7 = \frac{\hbar}{m_e r_7}$ (Eq. (1.35)) and $s = \frac{1}{2}$ into Eq. (13.672) gives:

$$\frac{\hbar^2}{m_e r_7^3} = \frac{(Z-6)e^2}{4\pi\varepsilon_0 r_7^2} - \frac{3\hbar^2}{12m_e r_7^2 r_3}\sqrt{\frac{3}{4}} + \frac{2\hbar^2}{Zm_e r_7^2 r_3}\sqrt{\frac{3}{4}} - \left[\frac{Z-7}{Z-6}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_7^4 m_e}10\sqrt{\frac{3}{4}} \tag{13.673}$$

The quadratic equation corresponding to Eq. (13.673) is:

$$r_7^2-\frac{\frac{\hbar^2}{m_e}}{\left(\frac{(Z-6)e^2}{4\pi\varepsilon_0}-\left(\frac{3}{12}-\frac{2}{Z}\right)\frac{\hbar^2}{m_e r_3}\sqrt{\frac{3}{4}}\right)}r_7-\frac{\frac{\hbar^2}{m_e}\left[\frac{Z-7}{Z-6}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3 10\sqrt{\frac{3}{4}}}{\left(\frac{(Z-6)e^2}{4\pi\varepsilon_0}-\left(\frac{3}{12}-\frac{2}{Z}\right)\frac{\hbar^2}{m_e r_3}\sqrt{\frac{3}{4}}\right)}=0 \quad (13.674)$$

The solution of Eq. (13.674) using the quadratic formula is:

$$r_7=\frac{\frac{a_0}{\left((Z-6)-\left(\frac{3}{12}-\frac{2}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}\pm a_0\sqrt{\left(\frac{1}{\left((Z-6)-\left(\frac{3}{12}-\frac{2}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}\right)^2+\frac{20\sqrt{3}\left(\left[\frac{Z-7}{Z-6}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3\right)}{\left((Z-6)-\left(\frac{3}{12}-\frac{2}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}}}{2},\ r_3 \text{ in units of } a_0 \quad (13.675)$$

The positive root of Eq. (13.675) must be taken in order that $r_7>0$. Substitution of $\frac{r_3}{a_0}=0.59020$ (Eq. (10.62) with $Z=8$) into Eq. (13.675) gives:

$$r_7=0.91088a_0 \quad (13.676)$$

ENERGIES OF THE $2p$ SHELL OF THE OXYGEN ATOMS OF THE OXYGEN MOLECULE

The central forces on the $2p$ shell of each O are increased with the formation of the σ MO, which reduces the shell's radius and increases its total energy. The Coulombic energy terms of the total energy of the two O atoms at the new radius are calculated and added to the energy of the σ MO to give the total energy of O_2. Then, the bond energy is determined from the total O_2 energy.

The radius r_8 of each oxygen atom before bonding is given by Eq. (10.162).

$$r_8=a_0 \quad (13.677)$$

Using the initial radius r_8 of each O atom and the final radius r_7 of the $O2p$ shell of O_2 (Eq. (13.676)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_T(O_2,2p)$ of the Coulombic energy change of the $O2p$ electrons of both atoms is determined using Eq. (10.102):

$$\begin{aligned}E_T(O_2,2p)&=-2\sum_{n=4}^{6}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_7}-\frac{1}{r_8}\right) \quad (13.678)\\&=-2(13.60580\ eV)(0.09784)(2+3+4)=-23.96074\ eV\end{aligned}$$

FORCE BALANCE OF THE σ MO OF THE OXYGEN MOLECULE

The force balance equation for the σ-MO of the oxygen molecule given by Eq. (11.200) and Eqs. (13.633-13.634) with $n_e=3$ and $|L|=\sqrt{\frac{3}{4}}\hbar$ is:

$$\frac{\hbar^2}{m_e a^2 b^2}D=\frac{e^2}{8\pi\varepsilon_0 ab^2}D+\frac{\hbar^2}{2m_e a^2 b^2}D-\left(\frac{3}{2}+\frac{\sqrt{\frac{3}{4}}}{Z}\right)\frac{\hbar^2}{2m_e a^2 b^2}D \quad (13.679)$$

$$\frac{\hbar^2}{m_e a^2 b^2}D=\frac{e^2}{8\pi\varepsilon_0 ab^2}D-\left(\frac{1}{2}+\frac{\sqrt{\frac{3}{4}}}{Z}\right)\frac{\hbar^2}{2m_e a^2 b^2}D \quad (13.680)$$

$$\left(\frac{5}{2}+\frac{\sqrt{\frac{3}{4}}}{Z}\right)\frac{\hbar^2}{2m_e a^2 b^2}D=\frac{e^2}{8\pi\varepsilon_0 ab^2}D \tag{13.681}$$

$$a=\left(\frac{5}{2}+\frac{\sqrt{\frac{3}{4}}}{Z}\right)a_0 \tag{13.682}$$

Substitution of $Z=8$ into Eq. (13.682) gives:

$$a=2.60825a_0=1.38023\ X\ 10^{-10}\ m \tag{13.683}$$

Substitution of Eq. (13.683) into Eq. (11.79) is:

$$c'=1.14198a_0=6.04312\ X\ 10^{-11}\ m \tag{13.684}$$

The internuclear distance given by multiplying Eq. (13.684) by two is:

$$2c'=2.28397a_0=1.20862\ X\ 10^{-10}\ m \tag{13.685}$$

The experimental bond distance is [28] :

$$2c'=1.20752\ X\ 10^{-10}\ m \tag{13.686}$$

Substitution of Eqs. (13.683-13.684) into Eq. (11.80) is:

$$\begin{aligned} b=c&=2.34496a_0\\ &=1.24090\ X\ 10^{-10}\ m\end{aligned} \tag{13.687}$$

Substitution of Eqs. (13.683-13.684) into Eq. (11.67) is:

$$e=0.43783 \tag{13.688}$$

Using the electron configuration of O_2 (Eq. (13.667)), the radii of the $O1s=0.12739a_0$ (Eq. (10.51)), $O2s=0.59020a_0$ (Eq. (10.62)), and $O2p=0.91088a_0$ (Eq. (13.676)) shells and the parameters of the σ MO of O_2 given by Eqs. (13.3-13.4), (13.683-13.685), and (13.687-13.688), the dimensional diagram and charge-density of the O_2 MO are shown in Figures 13.16 and 13.17, respectively.

Figure 13.16. The cross section of the O_2 MO showing the axes, σ MO (H_2-type ellipsoidal MO), with the O $1s$, $2s$, and $2p$ atomic orbitals (AOs). Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, r_7: radius of the $O2p$ shell having two paired electrons.

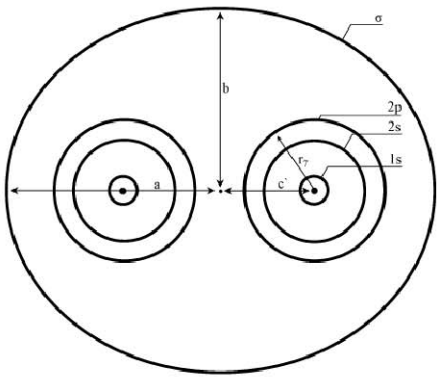

Figure 13.17. O_2 MO comprising the σ MO (H_2-type MO) with O atoms at the foci that have each donated an electron to the σ MO and have smaller radii and higher binding energies as a consequence. (A) Color scale, translucent view of the charge-density of the O_2 MO. (B) Off-center cut-away view showing the complete inner most $O1s$ shell, and moving radially, the $O2s$ shell, the $O2p$ shell, and the σ prolate spheroidal MO that have the O atoms as the foci.

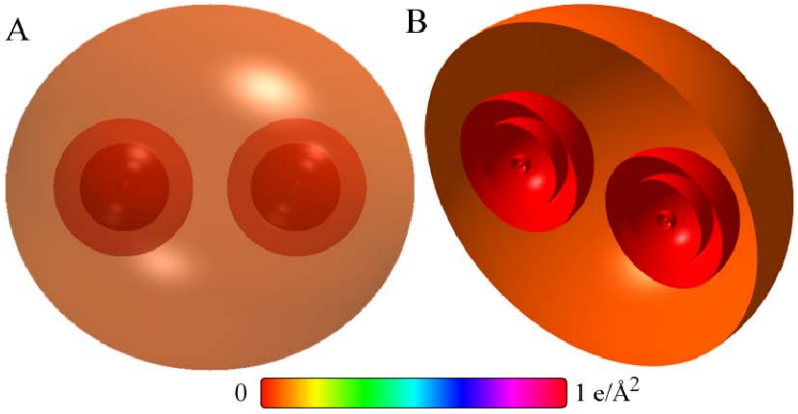

SUM OF THE ENERGIES OF THE σ MO AND THE AOs OF THE OXYGEN MOLECULE

The energies of the O_2 σ MO are given by the substitution of the semiprincipal axes (Eqs. (13.683-13.684) and (13.687)) into the energy equations (Eqs. (11.207-11.212)) of H_2:

$$V_e = \frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -22.37716\ eV \tag{13.689}$$

$$V_p = \frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 11.91418\ eV \tag{13.690}$$

$$T = \frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 4.28968\ eV \tag{13.691}$$

$$V_m = \frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -2.14484\ eV \tag{13.692}$$

$$E_T = V_e + T + V_m + V_p \tag{13.693}$$

Substitution of Eqs. (11.79) and (13.689-13.692) into Eq. (13.693) gives:

$$E_T(O_2,\sigma) = \frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2}}}\left(\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{2}}}{a-\sqrt{\frac{aa_0}{2}}}-1\right) = -8.31814\ eV \tag{13.694}$$

where $E_T(O_2,\sigma)$ is the total energy of the σ MO of O_2. The sum, $E_T(O_2)$, of $E_T(O_2,2p)$, the $2p$ AO contribution given by: Eq. (13.678), and $E_T(O_2,\sigma)$, the σ MO contribution given by Eq. (13.694) is:

$$E_T(O_2) = E_T(O_2,2p) + E_T(O_2,\sigma) = -23.96074\ eV - 8.31814\ eV = -32.27888\ eV \tag{13.695}$$

VIBRATION OF O_2

The vibrational energy levels of O_2 may be solved by determining the Morse potential curve from the energy relationships for the transition from two O atoms whose parameters are given by Eqs. (10.154-10.163) to the two O atoms whose parameter r_7 is given by Eq. (13.676) and the σ MO whose parameters are given by Eqs. (13.683-13.685) and (13.687-13.688). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K&P) [15] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

THE DOPPLER ENERGY TERMS OF THE OXYGEN MOLECULE

The equations of the radiation reaction force of oxygen are the same as those of H_2 with the substitution of the oxygen parameters. Using Eqs. (11.231-11.233), the angular frequency of the reentrant oscillation in the transition state is:

$$\omega = \sqrt{\frac{e^2}{4\pi\varepsilon_0 a^3}} = 9.81432\ X\ 10^{16}\ rad/s \tag{13.696}$$

where a is given by Eq. (13.683). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K = \hbar\omega = \hbar 9.81432\ X\ 10^{16}\ rad/s = 6.45996\ eV \tag{13.697}$$

In Eq. (11.181), substitution of $E_T(O_2)$ for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (13.697) for $\bar{E}_K$ gives the Doppler energy of the electrons of the reentrant orbit:

$$\bar{E}_D \cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}} = -32.27888\ eV\sqrt{\frac{2e(6.45996\ eV)}{m_e c^2}} = -0.16231\ eV \tag{13.698}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the O_2 MO due to the reentrant orbit in the transition state corresponding to simple

harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (13.698) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy. Using the experimental O_2 ω_e of 1580.19 cm^{-1} $(0.19592\ eV)$ [28] for $\bar{E}_{Kvib}$ of the transition state, $\bar{E}_{osc}(O_2)$ is:

$$\bar{E}_{osc}(O_2) = \bar{E}_D + \bar{E}_{Kvib} = \bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{13.699}$$

$$\bar{E}_{osc}(O_2) = -0.16231\ eV + \frac{1}{2}(0.19592\ eV) = -0.06435\ eV \tag{13.700}$$

TOTAL AND BOND ENERGIES OF THE OXYGEN MOLECULE

$E_{T+osc}(O_2)$, the total energy of O_2 including the Doppler term, is given by the sum of $E_T(O_2)$ (Eq. (13.695)) and $\bar{E}_{osc}(O_2)$ given by Eq. (13.700):

$$\begin{aligned} E_{T+osc}(O_2) &= V_e + T + V_m + V_p + E_T(O_2, 2p) + \bar{E}_{osc}(O_2) \\ &= E_T(O_2, \sigma) + E_T(O_2, 2p) + \bar{E}_{osc}(O_2) \\ &= E_T(O_2) + \bar{E}_{osc}(O_2) \end{aligned} \tag{13.701}$$

$$\begin{aligned} E_{T+osc}(O_2) = &\left\{ \left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2}}} \left(\left(2 - \frac{1}{2}\frac{a_0}{a}\right) \ln \frac{a + \sqrt{\frac{aa_0}{2}}}{a - \sqrt{\frac{aa_0}{2}}} - 1 \right) - 2\sum_{n=4}^{6} \frac{(Z-n)e^2}{8\pi\varepsilon_0} \left(\frac{1}{r_7} - \frac{1}{r_8} \right) \right) \right. \\ &\left. \left(1 + \sqrt{\frac{2\hbar\sqrt{\frac{e^2}{4\pi\varepsilon_0 a^3}}}{m_e c^2}} \right) + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \right\} \\ = &-32.27888\ eV - 0.16231\ eV + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \end{aligned} \tag{13.702}$$

From Eqs. (13.699-13.702), the total energy of the O_2 MO is:

$$\begin{aligned} E_{T+osc}(O_2) &= -32.27888\ eV + \bar{E}_{osc}(O_2) \\ &= -32.27888\ eV - 0.16231\ eV + \frac{1}{2}(0.19592\ eV) \\ &= -32.34323\ eV \end{aligned} \tag{13.703}$$

where the experimental ω_e was used for the $\hbar\sqrt{\frac{k}{\mu}}$ term.

The O_2 bond dissociation energy, $E_D(O_2)$, is given by the difference in the total energies of the two O atoms and $E_{T+osc}(O_2)$:

$$E_D(O_2) = 2E(O) - E_{T+osc}(O_2) \tag{13.704}$$

where the energy of an oxygen atom is [6]:

$$E(O) = -13.61806\ eV \tag{13.705}$$

Thus, the O_2 bond dissociation energy, $E_D(O_2)$, given by Eqs. (13.703-13.705) is:

$$E_D(O_2) = -2(13.61806\ eV) - E_{T+osc}(O_2) = -27.23612\ eV - (-32.34323\ eV) = 5.10711\ eV \tag{13.706}$$

The experimental O_2 bond dissociation energy from Ref. [46] and Ref. [47] is:

$$E_D(O_2) = 5.11665\ eV \tag{13.707}$$

$$E_D(O_2) = 5.116696\ eV \tag{13.708}$$

The results of the determination of bond parameters of O_2 are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

FLUORINE MOLECULE

The fluorine molecule can be formed by the reaction of two fluorine atoms:

$$F + F \rightarrow F_2 \tag{13.709}$$

The bond in the fluorine molecule comprises a H_2-type molecular orbital (MO) with two paired electrons. The force balance equation and radius r_9 of the $2p$ shell of F is derived in the Nine-Electron Atoms section. With the formation of the H_2-type MO by the contribution of a $2p$ electron from each F atom, a diamagnetic force arises between the remaining $2p$ electrons and the H_2-type MO. This force from each F causes the H_2-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the integer increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining $2p$ electrons of each F decrease the radius of the corresponding shell such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of F_2 is $1s_1^2 1s_2^2 2s_1^2 2s_2^2 2p_1^4 2p_2^4 \sigma_{1,2}^2$ where the subscript designates the F atom, 1 or 2, σ designates the H_2-type MO, and the orbital arrangement is:

σ state

$\uparrow\downarrow$

2p state

$\uparrow\downarrow$ $\uparrow\downarrow$ $\uparrow\downarrow$ $\uparrow\downarrow$

0 1 0 1

2s state

$\uparrow\downarrow$ $\uparrow\downarrow$

1s state

$\uparrow\downarrow$ $\uparrow\downarrow$

$F1$ $F2$

(13.710)

Fluorine is predicted to be diamagnetic in agreement with observations [42].

FORCE BALANCE OF THE $2p$ SHELL OF THE FLUORINE ATOMS OF THE FLUORINE MOLECULE

For each F atom, force balance for the outermost $2p$ electron of F_2 (electron 8) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 8 and the other $2p$-shell as well as the $2s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Nine-Electron Atoms section. The central Coulomb force on the outer-most $2p$ shell electron of F_2 (electron 8) due to the nucleus and the inner seven electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele} = \frac{(Z-7)e^2}{4\pi\varepsilon_0 r_8^2}\mathbf{i}_\mathbf{r} \tag{13.711}$$

for $r > r_7$. The $2p$ shell possess an external electric field given by Eq. (10.92) for $r > r_8$. The energy is minimized with conservation of angular momentum. This condition is met when the diamagnetic force, $\mathbf{F}_{diamagnetic}$, of Eq. (10.82) due to the p-orbital contributions is the same as that of the reactant fluorine atoms given by Eq. (10.176) with r_8 replacing r_9:

$$\begin{aligned}\mathbf{F}_{diamagnetic} &= -\left(\frac{2}{3}\right)\frac{\hbar^2}{4m_e r_8^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \\ &= -\frac{2\hbar^2}{12m_e r_8^2 r_3}\sqrt{\frac{3}{4}}\mathbf{i}_\mathbf{r}\end{aligned} \tag{13.712}$$

Thus, $\mathbf{F}_{diamagnetic}$ due to the two filled $2p$ orbitals per F atom is twice that of N_2 given by Eq. (13.622) having one filled $2p$ orbital per N atom. $\mathbf{F}_{mag\ 2}$ corresponding to the conserved spin and orbital angular momentum is also the same as that of the reactant fluorine atoms given by Eq. (10.177) and that of N_2 given by Eq. (13.623) where the outer radius of the $2p$ shell of the

F atoms of F_2 is r_8.

$$\mathbf{F}_{mag\ 2} = \frac{1}{Z}\frac{3\hbar^2}{m_e r_8^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.713}$$

The electric field external to the $2p$ shell given by Eq. (10.92) for $r > r_8$ gives rise to a second diamagnetic force, $\mathbf{F}_{diamagnetic\ 2}$, given by Eq. (10.93). $\mathbf{F}_{diamagnetic\ 2}$ due to the binding of the p-orbital electron having an electric field of +1 outside of its radius is :

$$\mathbf{F}_{diamagnetic\ 2} = -\left[\frac{Z-8}{Z-7}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{m_e r_8^4}10\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.714}$$

In addition, the contribution of a $2p$ electron from each F atom in the formation of the σ MO gives rise to a paramagnetic force on the remaining paired $2p$ electrons. The force $\mathbf{F}_{mag\ 3}$ is given by Eq. (13.625) wherein the radius is r_8:

$$\mathbf{F}_{mag\ 3} = \frac{\hbar^2}{4m_e r_8^3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.715}$$

The radius of the $2p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.711)) and diamagnetic (Eqs. (13.712) and (13.714)), and paramagnetic (Eqs. (13.713) and (13.715)) forces as follows:

$$\frac{m_e v_8^2}{r_8} = \begin{pmatrix} \frac{(Z-7)e^2}{4\pi\varepsilon_0 r_8^2} - \frac{2\hbar^2}{12 m_e r_8^2 r_3}\sqrt{s(s+1)} + \frac{3\hbar^2}{Z m_e r_8^2 r_3}\sqrt{s(s+1)} \\ -\left[\frac{Z-8}{Z-7}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_8^4 m_e}10\sqrt{s(s+1)} + \frac{\hbar^2}{4m_e r_8^3}\sqrt{s(s+1)} \end{pmatrix} \tag{13.716}$$

Substitution of $v_8 = \frac{\hbar}{m_e r_8}$ (Eq. (1.35)) and $s = \frac{1}{2}$ into Eq. (13.716) gives:

$$\frac{\hbar^2}{m_e r_8^3} - \frac{\hbar^2}{4m_e r_8^3}\sqrt{\frac{3}{4}} = \frac{(Z-7)e^2}{4\pi\varepsilon_0 r_8^2} - \frac{2\hbar^2}{12 m_e r_8^2 r_3}\sqrt{\frac{3}{4}} + \frac{3\hbar^2}{Z m_e r_8^2 r_3}\sqrt{\frac{3}{4}} - \left[\frac{Z-8}{Z-7}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_8^4 m_e}10\sqrt{\frac{3}{4}} \tag{13.717}$$

The quadratic equation corresponding to Eq. (13.717) is:

$$r_8^2 - \frac{\frac{\hbar^2}{m_e}\left(1-\frac{\sqrt{3}}{8}\right)}{\left(\frac{(Z-7)e^2}{4\pi\varepsilon_0} - \left(\frac{2}{12}-\frac{3}{Z}\right)\frac{\hbar^2}{m_e r_3}\sqrt{\frac{3}{4}}\right)}r_8 - \frac{\frac{\hbar^2}{m_e}\left[\frac{Z-8}{Z-7}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3 10\sqrt{\frac{3}{4}}}{\left(\frac{(Z-7)e^2}{4\pi\varepsilon_0} - \left(\frac{2}{12}-\frac{3}{Z}\right)\frac{\hbar^2}{m_e r_3}\sqrt{\frac{3}{4}}\right)} = 0 \tag{13.718}$$

The solution of Eq. (13.718) using the quadratic formula is:

$$r_8 = \frac{\frac{a_0\left(1-\frac{\sqrt{3}}{8}\right)}{\left((Z-7)-\left(\frac{2}{12}-\frac{3}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)} \pm a_0\sqrt{\left(\frac{1-\frac{\sqrt{3}}{8}}{\left((Z-7)-\left(\frac{2}{12}-\frac{3}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}\right)^2 + \frac{20\sqrt{3}\left(\left[\frac{Z-8}{Z-7}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3\right)}{\left((Z-7)-\left(\frac{2}{12}-\frac{3}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}}}{2}, \; r_3 \text{ in units of } a_0 \tag{13.719}$$

The positive root of Eq. (13.719) must be taken in order that $r_8 > 0$. Substitution of $\frac{r_3}{a_0} = 0.51382$ (Eq. (10.62) with $Z = 9$) into Eq. (13.719) gives:

$$r_8 = 0.73318 a_0 \tag{13.720}$$

ENERGIES OF THE $2p$ SHELL OF THE FLUORINE ATOMS OF THE FLUORINE MOLECULE

The central forces on the $2p$ shell of each F are increased with the formation of the σ MO, which reduces the shell's radius and increases its total energy. The Coulombic energy terms of the total energy of the two F atoms at the new radius are calculated and added to the energy of the σ MO to give the total energy of F_2. Then, the bond energy is determined from the total F_2 energy.

The radius r_9 of each fluorine atom before bonding is given by Eq. (10.182):

$$r_9 = 0.78069a_0 \tag{13.721}$$

Using the initial radius r_9 of each F atom and the final radius r_8 of the $F2p$ shell of F_2 (Eq. (13.720)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_T\left(F_2,2p\right)$ of the Coulombic energy change of the $F2p$ electrons of both atoms is determined using Eq. (10.102).

$$\begin{aligned} E_T\left(F_2,2p\right) &= -2\sum_{n=4}^{7}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_8}-\frac{1}{r_9}\right) \\ &= -2\left(13.60580\ eV\right)\left(0.08301\right)\left(2+3+4+5\right) = -31.62353\ eV \end{aligned} \tag{13.722}$$

FORCE BALANCE OF THE σ MO OF THE FLUORINE MOLECULE

The relativistic diamagnetic force $\mathbf{F}_{diamagneticMO2}$ of F_2 is one half that of N_2 due to the two versus one filled $2p$ orbitals per atom at the focus. The force balance equation for the σ-MO of the fluorine molecule is given by Eq. (11.200) and Eqs. (13.633-13.634) with the correction of 1/2 due the two $2p$ orbitals per F after Eqs. (10.2-10.11), $n_e = 5$, and $\left|L\right| = \hbar$:

$$\frac{\hbar^2}{m_e a^2 b^2}D = \frac{e^2}{8\pi\varepsilon_0 ab^2}D + \frac{\hbar^2}{2m_e a^2 b^2}D - \left(\frac{5}{2}+\frac{1}{2Z}\right)\frac{\hbar^2}{2m_e a^2 b^2}D \tag{13.723}$$

$$\frac{\hbar^2}{m_e a^2 b^2}D = \frac{e^2}{8\pi\varepsilon_0 ab^2}D - \left(\frac{3}{2}+\frac{1}{2Z}\right)\frac{\hbar^2}{2m_e a^2 b^2}D \tag{13.724}$$

$$\left(\frac{7}{2}+\frac{1}{2Z}\right)\frac{\hbar^2}{2m_e a^2 b^2}D = \frac{e^2}{8\pi\varepsilon_0 ab^2}D \tag{13.725}$$

$$a = \left(\frac{7}{2}+\frac{1}{2Z}\right)a_0 \tag{13.726}$$

Substitution of $Z = 9$ into Eq. (13.726) gives:

$$a = 3.55556a_0 = 1.88152\ X\ 10^{-10}\ m \tag{13.727}$$

Substitution of Eq. (13.727) into Eq. (11.79) is:

$$c' = 1.33333a_0 = 7.05569\ X\ 10^{-11}\ m \tag{13.728}$$

The internuclear distance given by multiplying Eq. (13.728) by two is:

$$2c' = 2.66667a_0 = 1.41114\ X\ 10^{-10}\ m \tag{13.729}$$

The experimental bond distance is [28] :

$$2c' = 1.41193\ X\ 10^{-10}\ m \tag{13.730}$$

Substitution of Eqs. (13.727-13.728) into Eq. (11.80) is:

$$b = c = 3.29609a_0 = 1.74421\ X\ 10^{-10}\ m \tag{13.731}$$

Substitution of Eqs. (13.727-13.728) into Eq. (11.67) is:

$$e = 0.37500 \tag{13.732}$$

Using the electron configuration of F_2 (Eq. (13.710)), the radii of the $F1s = 0.11297a_0$ (Eq. (10.51)), $F2s = 0.51382a_0$ (Eq. (10.62)), and $F2p = 0.73318a_0$ (Eq. (13.720)) shells and the parameters of the σ MO of F_2 given by Eqs. (13.3-13.4), (13.727-13.728), and (13.731-13.732), the dimensional diagram and charge-density of the F_2 MO are shown in Figures 13.18 and 13.19, respectively.

Figure 13.18. The cross section of the F_2 MO showing the axes, σ MO (H_2-type ellipsoidal MO), with the F $1s$, $2s$, and $2p$ atomic orbitals (AOs). Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, r_8: radius of the $F2p$ shell having two paired electrons.

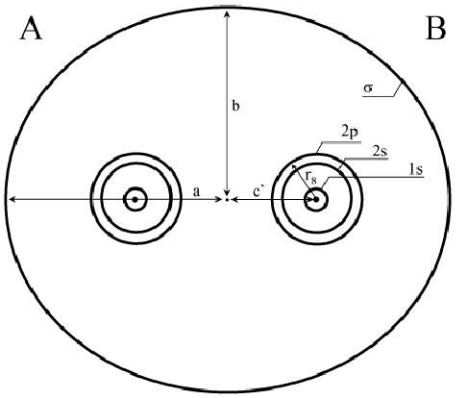

Figure 13.19. F_2 MO comprising the σ MO (H_2-type MO) with F atoms at the foci that have each donated an electron to the σ MO and have smaller radii and higher binding energies as a consequence. (A) Color scale, translucent view of the charge-density of the F_2 MO. (B) Off-center cut-away view showing the complete inner most $F1s$ shell, and moving radially, the $F2s$ shell, the $F2p$ shell, and the σ prolate spheroidal MO that have the F atoms as the foci.

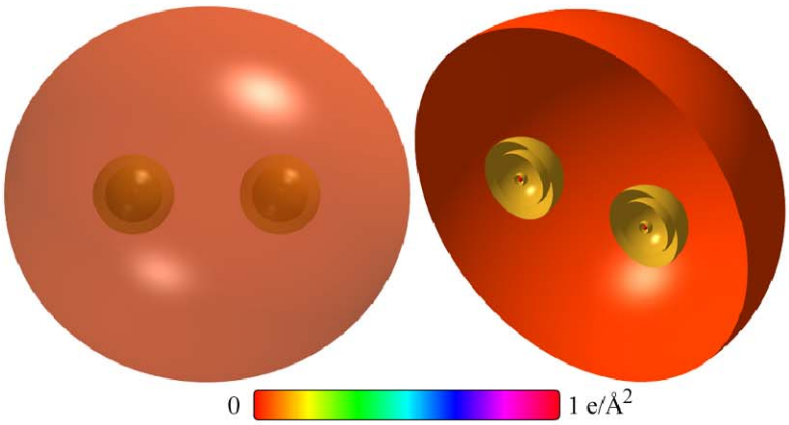

SUM OF THE ENERGIES OF THE σ MO AND THE AOs OF THE FLUORINE MOLECULE

The energies of the F_2 σ MO are given by the substitution of the semiprincipal axes (Eqs. (13.683-13.684) and (13.687)) into the energy equations (Eqs. (11.207-11.212)) of H_2:

$$V_e = \frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -16.09139\ eV \tag{13.733}$$

$$V_p = \frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 10.20435\ eV \tag{13.734}$$

$$T = \frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 2.26285\ eV \tag{13.735}$$

$$V_m = \frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -1.13143\ eV \tag{13.736}$$

$$E_T = V_e + T + V_m + V_p \tag{13.737}$$

Substitution of Eqs. (11.79) and (13.733-13.736) into Eq. (13.737) gives:

$$\begin{aligned} E_T(F_2,\sigma) &= \frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2}}}\left(\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{2}}}{a-\sqrt{\frac{aa_0}{2}}}-1\right) \\ &= -4.75562\ eV \end{aligned} \tag{13.738}$$

where $E_T(F_2,\sigma)$ is the total energy of the σ MO of F_2. The sum, $E_T(F_2)$, of $E_T(F_2,2p)$, the $2p$ AO contribution given by Eq. (13.722), and $E_T(F_2,\sigma)$, the σ MO contribution given by Eq. (13.738) is:

$$\begin{aligned} E_T(F_2) &= E_T(F_2,2p) + E_T(F_2,\sigma) \\ &= -31.62353\ eV - 4.75562\ eV = -36.37915\ eV \end{aligned} \tag{13.739}$$

VIBRATION OF F_2

The vibrational energy levels of F_2 may be solved by determining the Morse potential curve from the energy relationships for the transition from two F atoms whose parameters are given by Eqs. (10.174-10.183) to the two F atoms whose parameter r_8 is given by Eq. (13.720) and the σ MO whose parameters are given by Eqs. (13.727-13.729) and (13.731-13.732). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K&P) [15] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

THE DOPPLER ENERGY TERMS OF THE FLUORINE MOLECULE

The equations of the radiation reaction force of fluorine are the same as those of H_2 with the substitution of the fluorine parameters. Using Eqs. (11.231-11.233), the angular frequency of the reentrant oscillation in the transition state is:

$$\omega = \sqrt{\frac{e^2}{4\pi\varepsilon_0 a^3 m_e}} = 6.16629\ X\ 10^{15}\ rad/s \tag{13.740}$$

where a is given by Eq. (13.727). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)):

$$\bar{E}_K = \hbar\omega = \hbar 6.16629\ X\ 10^{15}\ rad/s = 4.05876\ eV \tag{13.741}$$

In Eq. (11.181), substitution of $E_T(F_2)$ for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (13.741) for $\bar{E}_K$ gives the Doppler energy of the electrons of the reentrant orbit:

$$\bar{E}_D \cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}} = -36.37915\ eV\sqrt{\frac{2e(4.05876\ eV)}{m_e c^2}} = -0.14499\ eV \tag{13.742}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the F_2 MO due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (13.742) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy. Using the experimental F_2 ω_e of 916.64 cm^{-1} $(0.11365\ eV)$ [28] for $\bar{E}_{Kvib}$ of the transition state, $\bar{E}_{osc}(F_2)$ is:

$$\bar{E}_{osc}(F_2) = \bar{E}_D + \bar{E}_{Kvib} = \bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{13.743}$$

$$\bar{E}_{osc}(F_2) = -0.14499\ eV + \frac{1}{2}(0.11365\ eV) = -0.08817\ eV \tag{13.744}$$

TOTAL AND BOND ENERGIES OF THE FLUORINE MOLECULE

$E_{T+osc}(F_2)$, the total energy of F_2 including the Doppler term, is given by the sum of $E_T(F_2)$ (Eq. (13.739)) and $\bar{E}_{osc}(F_2)$ given by Eq. (13.744):

$$\begin{aligned} E_{T+osc}(F_2) &= V_e + T + V_m + V_p + E_T(F_2, 2p) + \bar{E}_{osc}(F_2) \\ &= E_T(F_2, \sigma) + E_T(F_2, 2p) + \bar{E}_{osc}(F_2) \\ &= E_T(F_2) + \bar{E}_{osc}(F_2) \end{aligned} \tag{13.745}$$

$$E_{T+osc}(F_2) = \left\{ \begin{array}{l} \left(\dfrac{-e^2}{8\pi\varepsilon_0\sqrt{\dfrac{aa_0}{2}}} \left(\left(2 - \dfrac{1}{2}\dfrac{a_0}{a}\right) \ln \dfrac{a + \sqrt{\dfrac{aa_0}{2}}}{a - \sqrt{\dfrac{aa_0}{2}}} - 1 \right) - 2\sum_{n=4}^{7} \dfrac{(Z-n)e^2}{8\pi\varepsilon_0} \left(\dfrac{1}{r_8} - \dfrac{1}{r_9} \right) \right) \\ \left(1 + \sqrt{\dfrac{2\hbar\sqrt{\dfrac{e^2}{4\pi\varepsilon_0 a^3 m_e}}}{m_e c^2}} \right) + \dfrac{1}{2}\hbar\sqrt{\dfrac{k}{\mu}} \end{array} \right\} \tag{13.746}$$

$$= -36.37915\ eV - 0.14499\ eV + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}$$

From Eqs. (13.743-13.746), the total energy of the F_2 MO is:

$$E_{T+osc}(F_2) = -36.37915\ eV + \bar{E}_{osc}(F_2) = -36.37915\ eV - 0.14499\ eV + \frac{1}{2}(0.11365\ eV) = -36.46732\ eV \tag{13.747}$$

where the experimental ω_e was used for the $\hbar\sqrt{\frac{k}{\mu}}$ term.

The F_2 bond dissociation energy, $E_D(F_2)$, is given by the difference in the total energies of the two F atoms and $E_{T+osc}(F_2)$:

$$E_D(F_2) = 2E(F) - E_{T+osc}(F_2) \tag{13.748}$$

where the energy of a fluorine atom is [6]:

$$E(F) = -17.42282\ eV \tag{13.749}$$

Thus, the F_2 bond dissociation energy, $E_D(F_2)$, given by Eqs. (13.747-13.749) is:

$$E_D(F_2) = -2(17.42282\ eV) - E_{T+osc}(F_2) = -34.84564\ eV - (-36.46732\ eV) = 1.62168\ eV \tag{13.750}$$

The experimental F_2 bond dissociation energy is [48]:

$$E_D(F_2) = 1.606\ eV \tag{13.751}$$

The results of the determination of bond parameters of F_2 are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

CHLORINE MOLECULE

The chlorine molecule can be formed by the reaction of two chlorine atoms:

$$Cl + Cl \rightarrow Cl_2 \tag{13.752}$$

The chlorine molecule can be solved by using the hybridization approach used to solve the methane series $CH_{n=1,2,3,4}$. In the methane series, the $2s$ and $2p$ shells of carbon hybridize to form a single $2sp^3$ shell to achieve an energy minimum, and in a likewise manner, the $3s$ and $3p$ shells of chlorine hybridize to form a single $3sp^3$ shell which forms the bonding orbital of Cl_2.

FORCE BALANCE OF Cl_2

Cl_2 has two spin-paired electrons in a chemical bond between the chlorine atoms. The Cl_2 molecular orbital (MO) is determined by considering properties of the binding atoms and the boundary constraints. The prolate spheroidal H_2 MO developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules section satisfies the boundary constraints; thus, each Cl atom could contribute a $3p$ electron to form a σ MO (H_2-type ellipsoidal MO) as in the case of N_2, O_2, and F_2. However, such a bond is not possible with the outer Cl electrons in their ground state since the resulting $3p$ shells of chlorine atoms would overlap which is not energetically stable. Thus, when bonding, the chlorine $3s$ and $3p$ shells hybridize to form a single $3sp^3$ shell to achieve an energy minimum.

The Cl electron configuration given in the Seventeen-Electron Atoms section is $1s^2 2s^2 2p^6 3s^2 3p^5$, and the orbital arrangement is:

3p state

$$\underset{1}{\underline{\uparrow\downarrow}}\quad \underset{0}{\underline{\uparrow\downarrow}}\quad \underset{-1}{\underline{\uparrow}} \tag{13.753}$$

corresponding to the ground state $^2P^0_{3/2}$. The radius r_{17} of the $3p$ shell given by Eq. (10.363) is:

$$r_{17} = 1.05158a_0 \tag{13.754}$$

The energy of the chlorine $3p$ shell is the negative of the ionization energy of the chlorine atom given by Eq. (10.364). Experimentally, the energy is [6]:

$$E(3p\ shell) = -E(ionization;\ Cl) = -12.96764\ eV \tag{13.755}$$

The $Cl3s$ atomic orbital (AO) combines with the $Cl3p$ AOs to form a single $3sp^3$ hybridized orbital (HO) with the orbital arrangement.

$3sp^3$ state

$$\underset{0,0}{\underline{\uparrow\downarrow}}\quad \underset{1,-1}{\underline{\uparrow\downarrow}}\quad \underset{1,0}{\underline{\uparrow\downarrow}}\quad \underset{1,1}{\underline{\uparrow}} \tag{13.756}$$

where the quantum numbers (ℓ, m_ℓ) are below each electron. The total energy of the state is given by the sum over the seven electrons. Using only the largest-force terms of the outer most and next inner shell, the calculated energies for the chlorine atom and the ions: Cl, Cl^+, Cl^{2+}, Cl^{3+}, Cl^{4+}, Cl^{5+} and Cl^{6+} are given in Eqs. (10.363-10.364), (10.353-10.354), (10.331-10.332), (10.309-10.310), (10.288-10.289), (10.255-10.256), and (10.235-10.236), respectively. The sum $E_T\left(Cl,3sp^3\right)$ of the experimental energies of Cl and these ions is [6]:

$$E_T\left(Cl,3sp^3\right)=\begin{pmatrix}12.96764\ eV+23.814\ eV+39.61\ eV+53.4652\ eV\\ +67.8\ eV+97.03\ eV+114.1958\ eV\end{pmatrix}=408.88264\ eV \tag{13.757}$$

The spin and orbital-angular-momentum interactions cancel such that the energy of the $E_T\left(Cl,3sp^3\right)$ is purely Coulombic. By considering that the central field decreases by an integer for each successive electron of the shell, the radius r_{3sp^3} of the $Cl3sp^3$ shell may be calculated from the Coulombic energy using Eq. (10.102):

$$r_{3sp^3}=\sum_{n=10}^{16}\frac{(Z-n)e^2}{8\pi\varepsilon_0\left(e408.8826\ eV\right)}=\frac{28e^2}{8\pi\varepsilon_0\left(e408.8826\ eV\right)}=0.93172a_0 \tag{13.758}$$

where $Z=17$. Using Eqs. (10.102) and (13.758), the Coulombic energy $E_{Coulomb}\left(Cl,3sp^3\right)$ of the outer electron of the $Cl3sp^3$ shell is:

$$E_{Coulomb}\left(Cl,3sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{3sp^3}}=\frac{-e^2}{8\pi\varepsilon_0 0.93172a_0}=-14.60295\ eV \tag{13.759}$$

The calculated energy of the $C2sp^3$ shell of $14.63489\ eV$ given by Eq. (13.428), and nitrogen's calculated energy of $14.61664\ eV$ given by Eq. (10.143) is a close match with $E_{Coulomb}\left(Cl,3sp^3\right)$.

The unpaired $Cl3sp^3$ electrons from each of two chlorine atoms combine to form a molecular orbital. The nuclei of the Cl atoms are along the internuclear axis and serve as the foci. Due to symmetry, the other Cl electrons are equivalent to point charges at the origin. (See Eqs. (19-38) of Appendix II.) Thus, the energies in the Cl MO involve only the two $Cl3sp^3$ electrons. The forces are determined by these energies.

As in the case of H_2, the MO is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $Cl3sp^3$ HO for distances shorter than the radius of the $Cl3sp^3$ shell of each atom. Thus, the MO surface comprises a partial prolate spheroid in between the nuclei and is continuous with the $Cl3sp^3$ shell at each Cl atom. The energy of the H_2-type ellipsoidal MO is matched to that of the $Cl3sp^3$ shell. As in the case with OH, NH, and CH (where the latter also demonstrates sp^3 hybridization) the linear combination of the H_2-type ellipsoidal MO with each $Cl3sp^3$ HO must involve a 25% contribution from the H_2-type ellipsoidal MO to the $Cl3sp^3$ HO in order to match potential, kinetic, and orbital energy relationships. Thus, the Cl_2 MO must comprise two $Cl3sp^3$ HOs and 75% of a H_2-type ellipsoidal MO divided between the two $Cl3sp^3$ HOs:

$$2\ Cl3sp^3+0.75\ H_2\ MO\rightarrow Cl_2\ MO \tag{13.760}$$

The force balance of the Cl_2 MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.760) and the energy matching condition between the H_2-type-ellipsoidal-MO and $Cl3sp^3$-HO components of the MO.

As in the case with OH (Eq. (13.57)), NH (Eq. (13.247)), and CH (Eq. (13.429)), the H_2-type ellipsoidal MO comprises 75% of the Cl_2 MO; so, the electron charge density in Eq. (11.65) is given by $-0.75e$. Since the chlorine atoms of Cl_2 are hybridized and the k parameter is different from unity in order to meet the boundary constraints, both k and k' must comprise the corresponding hybridization factors. (In contrast, the chlorine atom of a $C-Cl$ bond of an alkyl chloride is not hybridized, and only k' must comprise the corresponding hybridization factor.) The force constant k' to determine the ellipsoidal parameter c' in terms of the central force of the foci is given by Eq. (13.59), except that k' is divided by two since the H_2-type-ellipsoidal-MO is physically divided between two $Cl3sp^3$ HOs. In addition, the energy matching at both $Cl3sp^3$ HOs further requires that k' be corrected with the hybridization factor given by Eq. (13.762). Thus, k' of the H_2-type-ellipsoidal-MO component of the Cl_2 MO is:

$$k'=C_{Cl3sp^3HO}\frac{(0.75)}{2}\frac{2e^2}{4\pi\varepsilon_0}=0.93172\frac{(0.75)}{2}\frac{2e^2}{4\pi\varepsilon_0} \tag{13.761}$$

The distance from the origin to each focus c' is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $Cl-Cl$-bond $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of the Cl_2 MO. Since the Cl_2 MO comprises a H_2-type-ellipsoidal MO that transitions to the $Cl3sp^3$ HOs at each end of the molecule, the energy $E\left(Cl,3sp^3\right)$ in Eq. (13.759) adds to that of the H_2-type ellipsoidal MO to give the total energy of the Cl_2 MO. From the energy equation and the relationship between the axes, the dimensions of the Cl_2 MO are solved.

The energy components of V_e, V_p, T, and V_m are those of H_2 (Eqs. (11.207-11.211)) except that they are corrected for electron hybridization. Hybridization gives rise to the $Cl3sp^3$ HO-shell Coulombic energy $E_{Coulomb}\left(Cl,3sp^3\right)$ given by Eq. (13.759). To meet the equipotential condition of the union of the H_2-type-ellipsoidal-MO with each $Cl3sp^3$ HO, the electron energies are normalized by the ratio of $14.60295\,eV$, the magnitude of $E_{Coulomb}\left(Cl,3sp^3\right)$ given by Eq. (13.759), and $13.605804\,eV$, the magnitude of the Coulombic energy between the electron and proton of H given by Eq. (1.264). This normalizes the energies to match that of the Coulombic energy alone to meet the energy matching condition of the Cl_2 MO under the influence of the two $Cl3sp^3$ HOs bridged by the H_2-type-ellipsoidal MO. The hybridization energy factor C_{Cl3sp^3HO} is:

$$C_{Cl3sp^3HO}=\frac{\frac{e^2}{8\pi\varepsilon_0 a_0}}{\frac{e^2}{8\pi\varepsilon_0 r_{3sp^3}}}=\frac{\frac{e^2}{8\pi\varepsilon_0 a_0}}{\frac{e^2}{8\pi\varepsilon_0 0.93172a_0}}$$
$$=\frac{13.605804\ eV}{14.60295\ eV}=0.93172 \tag{13.762}$$

The total energy $E_T\left(Cl_2\right)$ of the Cl_2 MO is given by the sum of the energies of the orbitals, the H_2-type ellipsoidal MO and the two $Cl3sp^3$ HOs, that form the hybridized Cl_2 MO. $E_T\left(Cl_2\right)$ follows from Eq. (13.74) for OH, but the energy of the $Cl3sp^3$ HO given by Eq. (13.759) is substituted for the energy of O and the H_2-type-ellipsoidal-MO energies are those of H_2 (Eqs. (11.207-11.212)) multiplied by the electron hybridization factor rather than by the factor of 0.75:

$$E_T\left(Cl_2\right)=E_T+E_{Coulomb}\left(Cl,3sp^3\right)$$
$$=-\frac{e^2}{8\pi\varepsilon_0 c'}\left[(0.93172)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-14.60295\ eV \tag{13.763}$$

To match the boundary condition that the total energy of the entire the H_2-type ellipsoidal MO is given by Eqs. (11.212) and (13.75), $E_T\left(Cl_2\right)$ given by Eq. (13.763) is set equal to Eq. (13.75):

$$E_T\left(Cl_2\right)=-\frac{e^2}{8\pi\varepsilon_0 c'}\left[(0.93172)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-14.60295\ eV$$
$$=-31.63537\ eV \tag{13.764}$$

From the energy relationship given by Eq. (13.764) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the Cl_2 MO can be solved.

Substitution of Eqs. (13.60) and (13.761) into Eq. (13.764) gives:

$$\frac{e^2}{8\pi\varepsilon_0\sqrt{\frac{4aa_0}{3(0.93172)}}}\left[(0.93172)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{4aa_0}{3(0.93172)}}}{a-\sqrt{\frac{4aa_0}{3(0.93172)}}}-1\right]=e17.03242 \tag{13.765}$$

The most convenient way to solve Eq. (13.765) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a=2.46500a_0=1.30442\ X\ 10^{-10}\ m \tag{13.766}$$

Substitution of Eq. (13.766) into Eq. (13.60) gives:

$$c'=1.87817a_0=9.93887\ X\ 10^{-11}\ m \tag{13.767}$$

The internuclear distance given by multiplying Eq. (13.767) by two is:

$$2c' = 3.75635a_0 = 1.98777\ X\ 10^{-10}\ m \tag{13.768}$$

The experimental bond distance is [28] :

$$2c' = 1.988\ X\ 10^{-10}\ m \tag{13.769}$$

Substitution of Eqs. (13.766-13.767) into Eq. (13.62) gives:

$$b = c = 1.59646a_0 = 8.44810\ X\ 10^{-11}\ m \tag{13.770}$$

Substitution of Eqs. (13.766-13.767) into Eq. (13.63) gives:

$$e = 0.76194 \tag{13.771}$$

The Cl nuclei comprise the foci of the H_2-type ellipsoidal MO. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $Cl3sp^3$ HO are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where $r_n = r_{3sp^3} = 0.93172a_0$ is the radius of the $Cl3sp^3$ shell. Substitution of Eqs. (13.766-13.767) into Eq. (13.261) gives

$$\theta' = 81.72° \tag{13.772}$$

Then, the angle θ_{Cl3sp^3HO} the radial vector of the $Cl3sp^3$ HO makes with the internuclear axis is:

$$\theta_{Cl3sp^3HO} = 180° - 81.72° = 98.28° \tag{13.773}$$

as shown in Figure 13.20. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{H_2MO}$ satisfies the following relationship:

$$r_{3sp^3} \sin\theta_{Cl3sp^3HO} = 0.93172a_0 \sin\theta_{Cl3sp^3HO} = b \sin\theta_{H_2MO} \tag{13.774}$$

such that

$$\theta_{H_2MO} = \sin^{-1}\frac{0.93172a_0 \sin\theta_{Cl3sp^3HO}}{b} = \sin^{-1}\frac{0.93172a_0 \sin 98.28°}{b} \tag{13.775}$$

with the use of Eq. (13.773). Substitution of Eq. (13.770) into Eq. (13.775) gives:

$$\theta_{H_2MO} = 35.28° \tag{13.776}$$

Then, the distance d_{H_2MO} along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$d_{H_2MO} = a\cos\theta_{H_2MO} \tag{13.777}$$

Substitution of Eqs. (13.766) and (13.776) into Eq. (13.777) gives:

$$d_{H_2MO} = 2.01235a_0 = 1.06489\ X\ 10^{-10}\ m \tag{13.778}$$

The distance d_{Cl3sp^3HO} along the internuclear axis from the origin of each Cl atom to the point of intersection of the orbitals is given by:

$$d_{Cl3sp^3HO} = d_{H_2MO} - c' \tag{13.779}$$

Substitution of Eqs. (13.768) and (13.778) into Eq. (13.779) gives:

$$d_{Cl3sp^3HO} = 0.13417a_0 = 7.10022\ X\ 10^{-12}\ m \tag{13.780}$$

As shown in Eq. (13.760), a factor of 0.25 of the charge-density of the H_2-type ellipsoidal MO is distributed on each $Cl3sp^3$ HO. Using the orbital composition of Cl_2 (Eq. (13.760)), the radii of the $Cl1s = 0.05932a_0$ (Eq. (10.51)), $Cl2s = 0.25344a_0$ (Eq. (10.62)), $Cl2p = 0.31190a_0$ (Eq. (10.212)), and $Cl3sp^3 = 0.93172a_0$ (Eq. (13.758)) shells, and the parameters of the Cl_2 MO given by Eqs. (13.3-13.4), (13.766-13.768), and (13.770-13.771), the dimensional diagram and charge-density of the Cl_2 MO comprising the linear combination of the H_2-type ellipsoidal MO and two $Cl3sp^3$ HOs according to Eq. (13.760) are shown in Figures 13.20 and 13.21, respectively.

Figure 13.20. The cross section of the Cl_2 MO showing the axes, angles, and point of intersection of the H_2-type ellipsoidal MO with the two $Cl3sp^3$ HOs. The continuation of the H_2-type-ellipsoidal-MO basis element beyond the intersection point with each $Cl3sp^3$ shell is shown as dashed since it only serves to solve the energy match with each $Cl3sp^3$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of the intersection points. The actual charge density is shown by the solid lines. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, $d_1 : d_{H_2MO}$, $\theta_1 : \theta_{Cl3sp^3HO}$, $d_2 : d_{Cl3sp^3HO}$, and $R : r_{3sp^3}$.

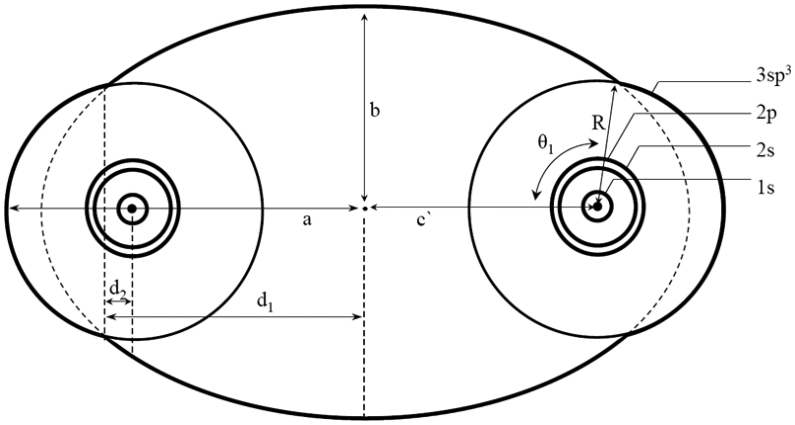

Figure 13.21. Cl_2 MO comprising the superposition of the H_2-type ellipsoidal MO and the two $Cl3sp^3$ HOs, each with a relative charge-density of 0.75 to 1.25 divided between the former and the latter; otherwise, the $Cl3sp^3$ HO is unchanged. (A) Side-on, color scale, translucent view of the charge-density of the Cl_2 MO. The ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $Cl3sp^3$ HO, the $Cl3sp^3$ HO, and the $Cl1s$, $Cl2s$, and $Cl2p$ shells of each Cl atom are shown. (B) Cut-away view showing the inner most $Cl1s$ shell, and moving radially, the $Cl2s$, $Cl2p$, and $Cl3sp^3$ shells, and the H_2-type ellipsoidal MO that transitions to the $Cl3sp^3$ HOs.

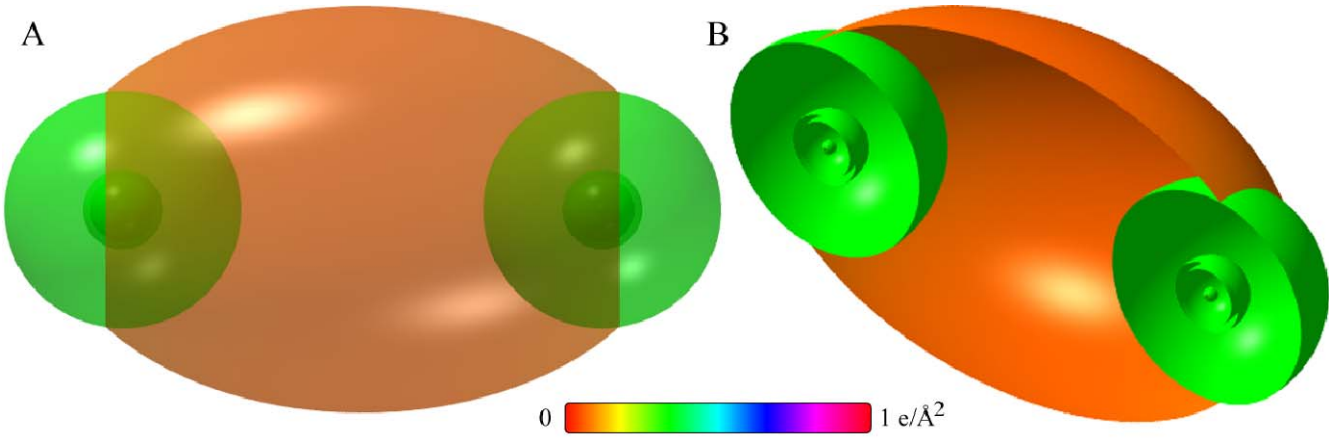

ENERGIES OF Cl_2

The energies of Cl_2 are given by the substitution of the semiprincipal axes (Eqs. (13.766-13.767) and (13.770)) into the energy equations, (Eq. (13.763) and Eqs. (11.207-11.211) of H_2) that are corrected for electron hybridization using Eq. (13.762).

$$V_e = (0.93172)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -27.02007\ eV \tag{13.781}$$

$$V_p = \frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 7.24416\ eV \tag{13.782}$$

$$T = (0.93172)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 5.48074\ eV \tag{13.783}$$

$$V_m = (0.93172)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -2.74037\ eV \tag{13.784}$$

$$E_T\left({}^{35}Cl_2\right) = -\frac{e^2}{8\pi\varepsilon_0 c'}\left[(0.93172)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right] - 14.60295\ eV = -31.63537\ eV \tag{13.785}$$

where $E_T(Cl_2)$ is given by Eq. (13.763) which is reiteratively matched to Eq. (13.75) within five-significant-figure round-off error.

VIBRATION AND ROTATION OF Cl_2

In Cl_2, the division of the H_2-type ellipsoidal MO between the two $Cl3sp^3$ HOs and the hybridization must be considered in determining the vibrational parameters. One approach is to use Eq. (13.761) for the force constant and r_{3sp^3} given by Eq. (13.758) for the distance parameter of the central force in Eq. (11.213) since the H_2-type ellipsoidal MO is energy matched to the $Cl3sp^3$ HOs. With the substitution of the Cl_2 parameters in Eqs. (11.213-11.217), the angular frequency of the oscillation is:

$$\begin{aligned}\omega &= \sqrt{\frac{0.93172\frac{(0.75)}{2}\frac{e^2}{8\pi\varepsilon_0\left(r_{3sp^3}\right)^3}-\frac{e^2}{8\pi\varepsilon_0\left(r_{3sp^3}+c'\right)^3}}{\mu}} \\ &= \sqrt{\frac{0.93172\frac{(0.75)}{2}\frac{e^2}{8\pi\varepsilon_0(0.93172)^3}-\frac{e^2}{8\pi\varepsilon_0(0.93172a_0+1.87817a_0)^3}}{\frac{35}{2}m_p}} = 1.01438\ X\ 10^{14}\ rad/s\end{aligned} \tag{13.786}$$

where c' is given by Eq. (13.767), and the reduced mass of ${}^{35}Cl_2$ is given by:

$$\mu_{{}^{35}Cl_2} = \frac{m_1 m_2}{m_1+m_2} = \frac{(35)(35)}{35+35}m_p \tag{13.787}$$

where m_p is the proton mass. Thus, during bond formation, the perturbation of the orbit determined by an inverse-squared force results in simple harmonic oscillatory motion of the orbit, and the corresponding frequency, $\omega(0)$, for ${}^{35}Cl_2$ given by Eqs. (11.136), (11.148), and (13.786) is:

$$\omega(0) = \sqrt{\frac{k(0)}{\mu}} = \sqrt{\frac{301.19\ Nm^{-1}}{\mu}} = 1.01438\ X\ 10^{14}\ radians/s \tag{13.788}$$

where the reduced nuclear mass of ${}^{35}Cl_2$ is given by Eq. (13.787) and the spring constant, $k(0)$, given by Eqs. (11.136) and (13.786) is:

$$k(0) = 301.19\ Nm^{-1} \tag{13.789}$$

The ${}^{35}Cl_2$ transition-state vibrational energy, $E_{vib}(0)$ or ω_e, given by Planck's equation (Eq. (11.127)) is:

$$E_{vib}(0) = \omega_e = \hbar\omega = \hbar 1.01438\ X\ 10^{14}\ rad/s = 0.06677\ eV = 538.52\ cm^{-1} \tag{13.790}$$

ω_e, from the experimental curve fit of the vibrational energies of $^{35}Cl_2$ is [28] :

$$\omega_e = 559.7\ cm^{-1} \tag{13.791}$$

Using Eqs. (13.112-13.118) with $E_{vib}(0)$ given by Eq. (13.790) and D_0 given by Eq. (13.807), the $^{35}Cl_2$ $\upsilon = 1 \rightarrow \upsilon = 0$ vibrational energy, $E_{vib}(1)$ is:

$$E_{vib}(1) = 0.0659\ eV \qquad (531.70\ cm^{-1}) \tag{13.792}$$

The experimental vibrational energy of $^{35}Cl_2$ using ω_e and $\omega_e x_e$ [28] according to K&P [15] is:

$$E_{vib}(1) = 0.0664\ eV \qquad (535.55\ cm^{-1}) \tag{13.793}$$

Using Eq. (13.113) with $E_{vib}(1)$ given by Eq. (13.792) and D_0 given by Eq. (13.807), the anharmonic perturbation term, $\omega_0 x_0$, of $^{35}Cl_2$ is:

$$\omega_0 x_0 = 3.41\ cm^{-1} \tag{13.794}$$

The experimental anharmonic perturbation term, $\omega_0 x_0$, of $^{35}Cl_2$ [28] is:

$$\omega_0 x_0 = 2.68\ cm^{-1} \tag{13.795}$$

The vibrational energies of successive states are given by Eqs. (13.790), (13.112), and (13.794).

Using Eqs. (13.133-13.134) and the internuclear distance, $r = 2c'$, and reduced mass of $^{35}Cl_2$ given by Eqs. (13.768) and (13.787), respectively, the corresponding B_e is:

$$B_e = 0.2420\ cm^{-1} \tag{13.796}$$

The experimental B_e rotational parameter of $^{35}Cl_2$ is [28]:

$$B_e = 0.2440\ cm^{-1} \tag{13.797}$$

THE DOPPLER ENERGY TERMS OF Cl_2

The equations of the radiation reaction force of the symmetrical Cl_2 MO are the given by Eqs. (11.231-11.233) with the substitution of the Cl_2 parameters and the substitution of the force factor of Eq. (13.761). The angular frequency of the reentrant oscillation in the transition state is:

$$\omega = \sqrt{\frac{0.93172\frac{(0.75)}{2}\frac{e^2}{4\pi\varepsilon_0 a^3}}{m_e}} = 6.31418\ X\ 10^{15}\ rad/s \tag{13.798}$$

where a is given by Eq. (13.766). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K = \hbar\omega = \hbar 1.6.31418\ X\ 10^{15}\ rad/s = 4.15610\ eV \tag{13.799}$$

In Eq. (11.181), substitution of the total energy of Cl_2, $E_T(Cl_2)$, (Eq. (13.764)) for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (13.799) for $\bar{E}_K$ gives the Doppler energy of the electrons for the reentrant orbit:

$$\bar{E}_D \cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}} = -31.63537\ eV\sqrt{\frac{2e(4.15610\ eV)}{m_e c^2}} = -0.12759\ eV \tag{13.800}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of Cl_2 due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (13.800) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of Cl_2. Using the experimental $^{35}Cl_2$ ω_e of 559.7 cm^{-1} $(0.06939\ eV)$ [28] for $\bar{E}_{Kvib}$ of the transition state, $\bar{E}_{osc}(^{35}Cl_2)$ is:

$$\bar{E}_{osc}(^{35}Cl_2) = \bar{E}_D + \bar{E}_{Kvib} = \bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{13.801}$$

$$\bar{E}_{osc}(^{35}Cl_2) = -0.12759\ eV + \frac{1}{2}(0.06939\ eV) = -0.09289\ eV \tag{13.802}$$

TOTAL AND BOND ENERGIES OF Cl_2

$E_{T+osc}\left({}^{35}Cl_2\right)$, the total energy of the ${}^{35}Cl_2$ radical including the Doppler term, is given by the sum of $E_T\left(Cl_2\right)$ (Eq. (13.764)) and $\overline{E}_{osc}\left({}^{35}Cl_2\right)$ given by Eq. (13.802).

$$E_{T+osc}\left({}^{35}Cl_2\right)=V_e+T+V_m+V_p+E_{Coulomb}\left(Cl,3sp^3\right)+\overline{E}_{osc}\left({}^{35}Cl_2\right)=E_T\left(Cl_2\right)+\overline{E}_{osc}\left({}^{35}Cl_2\right) \tag{13.803}$$

$$\begin{aligned}E_{T+osc}\left({}^{35}Cl_2\right)&=\left\{\left(\frac{-e^2}{8\pi\varepsilon_0 c'}\left[\left(0.93172\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-14.60295\ eV\right)\right\}\\&\quad+\left\{\left(\sqrt{1+\sqrt{\frac{2\hbar\sqrt{\frac{0.93172\frac{\left(0.75\right)}{2}\frac{e^2}{4\pi\varepsilon_0 a^3}}{m_e}}}{m_e c^2}}}\right)+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right\}\\&=-31.63537\ eV-0.12759\ eV+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\end{aligned} \tag{13.804}$$

From Eqs. (13.801-13.804), the total energy of ${}^{35}Cl_2$ is:

$$\begin{aligned}E_{T+osc}\left({}^{35}Cl_2\right)&=-31.63537\ eV+\overline{E}_{osc}\left({}^{35}Cl_2\right)\\&=-31.63537\ eV-0.12759\ eV+\frac{1}{2}\left(0.06939\ eV\right)=-31.72826\ eV\end{aligned} \tag{13.805}$$

where the experimental ω_e (Eq. (13.791)) was used for the $\hbar\sqrt{\frac{k}{\mu}}$ term.

The Cl_2 bond dissociation energy, $E_D\left({}^{35}Cl_2\right)$, is given by the difference between the total energies of the two $Cl3sp^3$ HOs and $E_{T+osc}\left({}^{35}Cl_2\right)$:

$$E_D\left({}^{35}Cl_2\right)=2E_{Coulomb}\left(Cl,3sp^3\right)-E_{T+osc}\left({}^{35}Cl_2\right) \tag{13.806}$$

$E_{Coulomb}\left(Cl,3sp^3\right)$ is given by Eq. (13.759); thus, the ${}^{35}Cl_2$ bond dissociation energy, $E_D\left({}^{35}Cl_2\right)$, given by Eqs. (13.759) and (13.805-13.806) is

$$E_D\left({}^{35}Cl_2\right)=-2\left(14.60295\ eV\right)-E_{T+osc}\left({}^{35}Cl_2\right)=-29.20590\ eV-\left(-31.72826\ eV\right)=2.52236\ eV \tag{13.807}$$

The experimental ${}^{35}Cl_2$ bond dissociation energy is [49]:

$$E_D\left({}^{35}Cl_2\right)=2.51412\ eV \tag{13.808}$$

The results of the determination of bond parameters of Cl_2 are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

CARBON NITRIDE RADICAL

The carbon nitride radical can be formed by the reaction of carbon and nitrogen atoms:

$$C+N\rightarrow CN \tag{13.809}$$

The bond in carbon nitride radical comprises a H_2-type molecular orbital (MO) with two paired electrons. The force balance equations and radii, r_6 and r_7, of the $2p$ shell of C and N are derived in the Six-Electron Atoms section and Seven-Electron Atoms section, respectively. With the formation of the H_2-type MO by the contribution of a $2p$ electron from each of the C and N atoms, a diamagnetic force arises between the remaining $2p$ electrons of each atom and the H_2-type MO. This force from each atom causes the H_2-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the integer increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining $2p$ electrons of each atom decrease the radii of the corresponding shells such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of CN is $C1s^2N1s^2C2s^2N2s^2C2p^1N2p^2\sigma_{C,N}^2$ where σ designates the H_2-type MO, and the orbital arrangement is:

σ state

$\underline{\uparrow\downarrow}$

2p state

$\underline{\uparrow}$ $\underline{\uparrow\downarrow}$

0 0

2s state

$\underline{\uparrow\downarrow}$ $\underline{\uparrow\downarrow}$

1s state

$\underline{\uparrow\downarrow}$ $\underline{\uparrow\downarrow}$

C N (13.810)

The carbon nitride radical is predicted to be weakly paramagnetic.

FORCE BALANCE OF THE $2p$ SHELL OF THE CARBON ATOM OF THE CARBON NITRIDE RADICAL

For the C atom, force balance for the outermost $2p$ electron of CN (electron 5) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 5 and the $2s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Six-Electron Atoms section. The central Coulomb force on the outer-most $2p$ shell electron of CN (electron 5) due to the nucleus and the inner four electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele} = \frac{(Z-4)e^2}{4\pi\varepsilon_0 r_5^2}\mathbf{i}_{\mathbf{r}} \tag{13.811}$$

for $r > r_4$. The $2p$ shell possess an external electric field given by Eq. (10.92) for $r > r_5$.

The single unpaired carbon $2p$ electron gives rise to a diamagnetic force on the σ-MO as given by Eqs. (13.835-13.839). The corresponding Newtonian reaction force cancels $\mathbf{F}_{diamagnetic}$, of Eq. (10.82). The energy is minimized with conservation of angular momentum. This condition is met when:

$$\mathbf{F}_{diamagnetic} = 0 \tag{13.812}$$

And, $\mathbf{F}_{mag\ 2}$ corresponding to the maximum orbital angular momentum of the three $2p$ orbitals given by Eq. (10.89) is:

$$\mathbf{F}_{mag\ 2} = \frac{1}{Z}\frac{3\hbar^2}{m_e r_5^2 r_3}\sqrt{s(s+1)}\mathbf{i}_{\mathbf{r}} \tag{13.813}$$

The electric field external to the $2p$ shell given by Eq. (10.92) for $r > r_5$ gives rise to a second diamagnetic force, $\mathbf{F}_{diamagnetic\ 2}$, given by Eq. (10.93). $\mathbf{F}_{diamagnetic\ 2}$ due to the binding of the p-orbital electron having an electric field of +1 outside of its radius is:

$$\mathbf{F}_{diamagnetic\ 2} = -\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{m_e r_5^4}10\sqrt{s(s+1)}\mathbf{i}_{\mathbf{r}} \tag{13.814}$$

The radius of the $2p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.811)) and diamagnetic (Eqs. (13.812) and (13.814)), and paramagnetic (Eq. (13.813)) forces as follows:

$$\frac{m_e v_5^2}{r_5} = \left(\begin{array}{l}\dfrac{(Z-4)e^2}{4\pi\varepsilon_0 r_5^2} + \dfrac{3\hbar^2}{Z m_e r_5^2 r_3}\sqrt{s(s+1)} \\ -\left[\dfrac{Z-5}{Z-4}\right]\left(1-\dfrac{\sqrt{2}}{2}\right)\dfrac{r_3\hbar^2}{r_5^4 m_e}10\sqrt{s(s+1)}\end{array}\right) \tag{13.815}$$

Substitution of $v_5 = \dfrac{\hbar}{m_e r_5}$ (Eq. (1.35)) and $s = \dfrac{1}{2}$ into Eq. (13.815) gives:

$$\frac{\hbar^2}{m_e r_5^3} = \frac{(Z-4)e^2}{4\pi\varepsilon_0 r_5^2} + \frac{3\hbar^2}{Z m_e r_5^2 r_3}\sqrt{\frac{3}{4}} - \left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_5^4 m_e}10\sqrt{\frac{3}{4}} \tag{13.816}$$

The quadratic equation corresponding to Eq. (13.816) is:

$$r_5^2-\frac{\frac{\hbar^2}{m_e}}{\left(\frac{(Z-4)e^2}{4\pi\varepsilon_0}+\frac{3\hbar^2}{Zm_e r_3}\sqrt{\frac{3}{4}}\right)}r_5-\frac{\frac{\hbar^2}{m_e}\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3 10\sqrt{\frac{3}{4}}}{\left(\frac{(Z-4)e^2}{4\pi\varepsilon_0}+\frac{3\hbar^2}{Zm_e r_3}\sqrt{\frac{3}{4}}\right)}=0 \tag{13.817}$$

The solution of Eq. (13.817) using the quadratic formula is:

$$r_5=\frac{\frac{a_0}{\left((Z-4)+\frac{3\sqrt{3}}{Z2r_3}\right)}\pm a_0\sqrt{\left(\frac{1}{\left((Z-4)+\frac{3\sqrt{3}}{Z2r_3}\right)}\right)^2+\frac{20\sqrt{3}\left(\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3\right)}{\left((Z-4)+\frac{3\sqrt{3}}{Z2r_3}\right)}}}{2},\ r_3\ \textit{in units of}\ a_0 \tag{13.818}$$

The positive root of Eq. (13.818) must be taken in order that $r_5>0$. Substitution of $\frac{r_3}{a_0}=0.84317$ (Eq. (10.62) with $Z=6$) into Eq. (13.818) gives:

$$r_5=0.88084a_0 \tag{13.819}$$

FORCE BALANCE OF THE $2p$ SHELL OF THE NITROGEN ATOM OF THE CARBON NITRIDE RADICAL

For the N atom, force balance for the outermost $2p$ electron of CN (electron 6) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 6 and the other $2p$-shell as well as the $2s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Seven-Electron Atoms section. The central Coulomb force on the outer-most $2p$ shell electron of CN (electron 6) due to the nucleus and the inner five electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele}=\frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2}\mathbf{i}_{\mathbf{r}} \tag{13.820}$$

for $r>r_5$. The $2p$ shell possess an external electric field given by Eq. (10.92) for $r>r_6$.

The forces to determine the radius of the $N2p$ shell of N in CN are the same as those of N in N_2 except that in CN there is a contribution from the Newtonian reaction force that arises from the single unpaired carbon $2p$ electron. The energy is minimized with conservation of angular momentum. This condition is met when $\mathbf{F}_{diamagnetic}$ of N in CN is canceled by the σ-MO -reaction force. Eq. (13.622) becomes:

$$\mathbf{F}_{diamagnetic}=0 \tag{13.821}$$

And, $\mathbf{F}_{mag\ 2}$ corresponding to the conserved orbital angular momentum of the three orbitals given by Eq. (10.89) is:

$$\mathbf{F}_{mag\ 2}=\frac{1}{Z}\frac{3\hbar^2}{m_e r_6^2 r_3}\sqrt{s(s+1)}\mathbf{i}_{\mathbf{r}} \tag{13.822}$$

The electric field external to the $2p$ shell given by Eq. (10.92) for $r>r_6$ gives rise to a second diamagnetic force, $\mathbf{F}_{diamagnetic\ 2}$, given by Eq. (10.93). $\mathbf{F}_{diamagnetic\ 2}$ due to the binding of the p-orbital electron having an electric field of +1 outside of its radius is:

$$\mathbf{F}_{diamagnetic\ 2}=-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{m_e r_6^4}10\sqrt{s(s+1)}\mathbf{i}_{\mathbf{r}} \tag{13.823}$$

The N forces $\mathbf{F}_{ele}$, $\mathbf{F}_{mag\ 2}$, $\mathbf{F}_{diamagnetic\ 2}$, and $\mathbf{F}_{mag\ 3}$ of CN are the same as those of N_2 given by Eqs. (13.621) and (13.623-13.624), respectively. In both cases, the contribution of a $2p$ electron from the N atom in the formation of the σ MO gives rise to a paramagnetic force on the remaining two $2p$ electrons that pair. Thus, the force, $\mathbf{F}_{mag\ 3}$ of CN, given by Eq. (13.625) is:

$$\mathbf{F}_{mag\ 3} = \frac{\hbar^2}{4m_e r_6^3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.824}$$

The radius of the $2p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.820)) and diamagnetic (Eqs. (13.821) and (13.823)), and paramagnetic (Eqs. (13.822) and (13.824)) forces as follows:

$$\frac{m_e v_6^2}{r_6} = \begin{pmatrix} \frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2} + \frac{3\hbar^2}{Zm_e r_6^2 r_3}\sqrt{s(s+1)} \\ -\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_6^4 m_e}10\sqrt{s(s+1)} + \frac{\hbar^2}{4m_e r_6^3}\sqrt{s(s+1)} \end{pmatrix} \tag{13.825}$$

Substitution of $v_6 = \frac{\hbar}{m_e r_6}$ (Eq. (1.35)) and $s = \frac{1}{2}$ into Eq. (13.626) gives:

$$\frac{\hbar^2}{m_e r_6^3} - \frac{\hbar^2}{4m_e r_6^3}\sqrt{\frac{3}{4}} = \frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2} + \frac{3\hbar^2}{Zm_e r_6^2 r_3}\sqrt{\frac{3}{4}} - \left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_6^4 m_e}10\sqrt{\frac{3}{4}} \tag{13.826}$$

The quadratic equation corresponding to Eq. (13.826) is

$$r_6^2 - \frac{\frac{\hbar^2}{m_e}\left(1-\frac{\sqrt{3}}{8}\right)}{\left(\frac{(Z-5)e^2}{4\pi\varepsilon_0} + \frac{3\hbar^2}{Zm_e r_3}\sqrt{\frac{3}{4}}\right)} r_6 - \frac{\frac{\hbar^2}{m_e}\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3 10\sqrt{\frac{3}{4}}}{\left(\frac{(Z-5)e^2}{4\pi\varepsilon_0} + \frac{3\hbar^2}{Zm_e r_3}\sqrt{\frac{3}{4}}\right)} = 0 \tag{13.827}$$

The solution of Eq. (13.827) using the quadratic formula is:

$$r_6 = \frac{\frac{a_0\left(1-\frac{\sqrt{3}}{8}\right)}{\left((Z-5)+\frac{3\sqrt{3}}{Z2r_3}\right)} \pm a_0\sqrt{\left(\frac{1-\frac{\sqrt{3}}{8}}{\left((Z-5)+\frac{3\sqrt{3}}{Z2r_3}\right)}\right)^2 + \frac{20\sqrt{3}\left(\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3\right)}{\left((Z-5)+\frac{3\sqrt{3}}{Z2r_3}\right)}}}{2},\ r_3 \textit{ in units of } a_0 \tag{13.828}$$

The positive root of Eq. (13.828) must be taken in order that $r_6 > 0$. Substitution of $\frac{r_3}{a_0} = 0.69385$ (Eq. (10.62) with $Z = 7$) into Eq. (13.828) gives:

$$r_6 = 0.76366a_0 \tag{13.829}$$

ENERGIES OF THE $2p$ SHELLS OF THE CARBON AND NITROGEN ATOMS OF THE CARBON NITRIDE RADICAL

The central forces on the $2p$ shell of the C and N atoms are increased with the formation of the σ MO which reduces each shell's radius and increases its total energy. The Coulombic energy terms of the total energy of the C and N atoms at the new radii are calculated and added to the energy of the σ MO to give the total energy of CN. Then, the bond energy is determined from the total CN energy.

The radius r_6 of the carbon atom before bonding is given by Eq. (10.122):

$$r_6 = 1.20654a_0 \tag{13.830}$$

Using the initial radius r_6 of the C atom and the final radius r_5 of the $C2p$ shell of CN (Eq. (13.819)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_T(CN, C2p)$ of the Coulombic energy change of the $C2p$ electron is determined using Eq. (10.102):

$$E_T\left(CN,C2p\right)=-\sum_{n=4}^{4}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_5}-\frac{1}{r_6}\right)=-\left(13.60580\ eV\right)\left(0.30647\right)\left(2\right)=-8.33948\ eV \tag{13.831}$$

The radius r_7 of the nitrogen atom before bonding is given by Eq. (10.142).

$$r_7=0.93084a_0 \tag{13.832}$$

Using the initial radius r_7 of the N atom and the final radius r_6 of the $N2p$ shell of CN (Eq. (13.829)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_T\left(CN,N2p\right)$ of the Coulombic energy change of the $N2p$ electron is determined using Eq. (10.102):

$$E_T\left(CN,N2p\right)=-\sum_{n=4}^{5}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_6}-\frac{1}{r_7}\right)=-\left(13.60580\ eV\right)\left(0.23518\right)\left(2+3\right)=-15.99929\ eV \tag{13.833}$$

FORCE BALANCE OF THE σ MO OF THE CARBON NITRIDE RADICAL

The diamagnetic force $\mathbf{F}_{diamagneticMO1}$ for the σ-MO of the CN molecule due to the two paired electrons in the $N2p$ shell given by Eq. (13.633) with $n_e=2$ is:

$$\mathbf{F}_{diamagneticMO1}=\frac{\hbar^2}{2m_ea^2b^2}D\mathbf{i}_\xi \tag{13.834}$$

The force $\mathbf{F}_{diamagneticMO2}$ is given by Eq. (13.634) except that the force is summed over the individual diamagnetic-force terms due to each component of angular momentum $\left|L_i\right|$ acting on the electrons of the σ-MO from each atom having a nucleus of charge Z_j at one of the foci of the σ-MO:

$$\mathbf{F}_{diamagneticMO2}=\sum_{i,j}\frac{\left|L_i\right|\hbar}{Z_j2m_ea^2b^2}D\mathbf{i}_\xi \tag{13.835}$$

Using Eqs. (11.200), (13.633-13.634), and (13.834-13.835), the force balance for the σ-MO of the carbon nitride radical comprising carbon with charge $Z_1=6$ and $\left|L_1\right|=\hbar$ and $\left|L_2\right|=\sqrt{\frac{3}{4}}\hbar$ and nitrogen with $Z_2=7$ and $\left|L_3\right|=\hbar$ is:

$$\frac{\hbar^2}{m_ea^2b^2}D=\frac{e^2}{8\pi\varepsilon_0ab^2}D+\frac{\hbar^2}{2m_ea^2b^2}D-\left(1+\frac{1}{Z_1}+\frac{\sqrt{\frac{3}{4}}}{Z_1}+\frac{1}{Z_2}\right)\frac{\hbar^2}{2m_ea^2b^2}D \tag{13.836}$$

$$\frac{\hbar^2}{m_ea^2b^2}D=\frac{e^2}{8\pi\varepsilon_0ab^2}D-\left(\frac{1}{Z_1}+\frac{\sqrt{\frac{3}{4}}}{Z_1}+\frac{1}{Z_2}\right)\frac{\hbar^2}{2m_ea^2b^2}D \tag{13.837}$$

$$\left(2+\frac{1}{Z_1}+\frac{\sqrt{\frac{3}{4}}}{Z_1}+\frac{1}{Z_2}\right)\frac{\hbar^2}{2m_ea^2b^2}D=\frac{e^2}{8\pi\varepsilon_0ab^2}D \tag{13.838}$$

$$a=\left(2+\frac{1}{Z_1}+\frac{\sqrt{\frac{3}{4}}}{Z_1}+\frac{1}{Z_2}\right)a_0 \tag{13.839}$$

Substitution of $Z_1=6$ and $Z_2=7$ into Eq. (13.839) gives:

$$a=2.45386a_0=1.29853\ X\ 10^{-10}\ m \tag{13.840}$$

Substitution of Eq. (13.840) into Eq. (11.79) is:

$$c'=1.10767a_0=5.86153\ X\ 10^{-11}\ m \tag{13.841}$$

The internuclear distance given by multiplying Eq. (13.841) by two is:

$$2c'=2.21534a_0=1.17231\ X\ 10^{-10}\ m \tag{13.842}$$

The experimental bond distance from Ref. [28] is:

$$2c'=1.17181\ X\ 10^{-10}\ m \tag{13.843}$$

Substitution of Eqs. (13.840-13.841) into Eq. (11.80) is:

$$b = c = 2.18964a_0 = 1.15871\ X\ 10^{-10}\ m \tag{13.844}$$

Substitution of Eqs. (13.840-13.841) into Eq. (11.67) is:

$$e = 0.45140 \tag{13.845}$$

Using the electron configuration of CN (Eq. (13.810)), the radii of the $C1s = 0.17113a_0$ (Eq. (10.51)), $C2s = 0.84317a_0$ (Eq. (10.62)), $C2p = 0.88084a_0$ (Eq. (13.819)), $N1s = 0.14605a_0$ (Eq. (10.51)), $N2s = 0.69385a_0$ (Eq. (10.62)), and $N2p = 0.76366a_0$ (Eq. (13.829)) shells and the parameters of the σ MO of CN given by Eqs. (13.3-13.4), (13.840-13.842), and (13.844-13.845), the dimensional diagram and charge-density of the CN MO are shown in Figures 13.22 and 13.23, respectively.

Figure 13.22. The cross section of the CN MO showing the axes, σ MO (H_2-type ellipsoidal MO), with the C $1s$, $2s$, and $2p$ atomic orbitals (AOs) and the N $1s$, $2s$, and $2p$ AOs. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, r_5: radius of the $C2p$ shell having one unpaired electron, r_6: radius of the $N2p$ shell having two paired electrons.

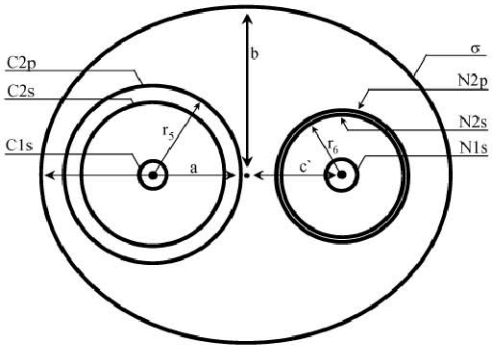

Figure 13.23. CN MO comprising the σ MO (H_2-type MO) with C and N atoms at the foci that have each donated an electron to the σ MO and have smaller radii and higher binding energies as a consequence. (A) Color scale, translucent view of the charge-density of the CN MO. (B) Off-center cut-away view showing the complete inner most $C1s$ shell, and moving radially, the $C2s$ shell, the $C2p$ shell, and the σ prolate spheroidal MO that has the C atom as a focus. Moving radially from the nitrogen-atom focus, the complete inner most $N1s$ shell, the $N2s$ shell, the $N2p$ shell, and the σ prolate spheroidal MO are shown.

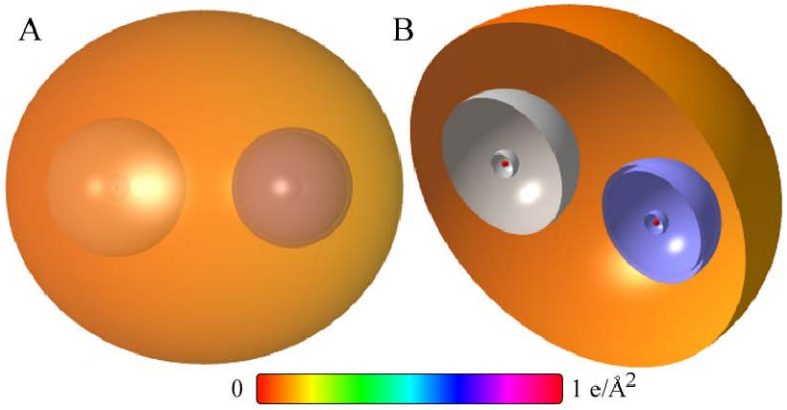

SUM OF THE ENERGIES OF THE σ MO AND THE AOs OF THE CARBON NITRIDE RADICAL

The energies of the CN σ MO are given by the substitution of the semiprincipal axes (Eqs. (13.840-13.841) and (13.844)) into the energy equations (Eqs. (11.207-11.212)) of H_2:

$$V_e = \frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -23.90105\ eV \tag{13.846}$$

$$V_p = \frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 12.28328\ eV \tag{13.847}$$

$$T = \frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 4.87009\ eV \tag{13.848}$$

$$V_m = \frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -2.43504\ eV \tag{13.849}$$

$$E_T = V_e + T + V_m + V_p \tag{13.850}$$

Substitution of Eqs. (11.79) and (13.846-13.849) into Eq. (13.850) gives:

$$E_T(CN,\sigma)=\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2}}}\left(\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{2}}}{a-\sqrt{\frac{aa_0}{2}}}-1\right)=-9.18273\ eV \tag{13.851}$$

where $E_T(CN,\sigma)$ is the total energy of the σ MO of CN. The sum, $E_T(CN)$, of $E_T(CN,C2p)$, the $C2p$ AO contribution given by Eq. (13.831), $E_T(CN,N2p)$, the $N2p$ AO contribution given by Eq. (13.833), and $E_T(CN,\sigma)$, the σ MO contribution given by Eq. (13.851) is:

$$\begin{aligned}E_T(CN)&=E_T(CN,C2p)+E_T(CN,N2p)+E_T(N_2,\sigma)\\&=-8.33948\ eV-15.99929\ eV-9.18273\ eV\\&=-33.52149\ eV\end{aligned} \tag{13.852}$$

VIBRATION OF *CN*

The vibrational energy levels of CN may be solved by determining the Morse potential curve from the energy relationships for the transition from a C atom and N atom whose parameters are given by Eqs. (10.115-10.123) and (10.134-10.143), respectively, to a C atom whose parameter r_5 is given by Eq. (10.819), a N atom whose parameter r_6 is given by Eq. (13.829), and the σ MO whose parameters are given by Eqs. (13.840-13.842) and (13.844-13.845). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K&P) [15] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

THE DOPPLER ENERGY TERMS OF THE CARBON NITRIDE RADICAL

The equations of the radiation reaction force of CN are the same as those of H_2 with the substitution of the CN parameters. Using Eqs. (11.231-11.233), the angular frequency of the reentrant oscillation in the transition state is:

$$\omega=\sqrt{\frac{\frac{e^2}{4\pi\varepsilon_0 a^3}}{m_e}}=1.07550\ X\ 10^{16}\ rad/s \tag{13.853}$$

where a is given by Eq. (13.840). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K=\hbar\omega=\hbar 1.07550\ X\ 10^{16}\ rad/s=7.07912\ eV \tag{13.854}$$

In Eq. (11.181), substitution of $E_T(CN)$ for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (13.854) for $\bar{E}_K$ gives the Doppler energy of the electrons of the reentrant orbit:

$$\begin{aligned}\bar{E}_D&\cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}}=-33.59603\ eV\sqrt{\frac{2e(7.07912\ eV)}{m_e c^2}}\\&=-0.17684\ eV\end{aligned} \tag{13.855}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the CN MO due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (13.855) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy. Using the experimental CN ω_e of 2068.59 cm^{-1} $(0.25647\ eV)$ [28] for $\bar{E}_{Kvib}$ of the transition state, $\bar{E}_{osc}(CN)$ is:

$$\begin{aligned}\bar{E}_{osc}(CN)&=\bar{E}_D+\bar{E}_{Kvib}\\&=\bar{E}_D+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\end{aligned} \tag{13.856}$$

$$\begin{aligned}\bar{E}_{osc}(CN)&=-0.17684\ eV+\frac{1}{2}(0.25647\ eV)\\&=-0.04860\ eV\end{aligned} \tag{13.857}$$

TOTAL AND BOND ENERGIES OF THE CARBON NITRIDE RADICAL

$E_{T+osc}(CN)$, the total energy of CN including the Doppler term, is given by the sum of $E_T(CN)$ (Eq. (13.852)) and $\bar{E}_{osc}(CN)$ given by Eq. (13.857):

$$\begin{aligned} E_{T+osc}(CN) &= V_e + T + V_m + V_p + E_T(CN, C2p) + E_T(CN, N2p) + \bar{E}_{osc}(CN) \\ &= E_T(CN, \sigma) + E_T(CN, C2p) + E_T(CN, N2p) + \bar{E}_{osc}(CN) \\ &= E_T(CN) + \bar{E}_{osc}(CN) \end{aligned} \tag{13.858}$$

$$\begin{aligned} E_{T+osc}(CN) = &\left\{ \begin{array}{l} \left(\dfrac{-e^2}{8\pi\varepsilon_0 \sqrt{\dfrac{aa_0}{2}}} \left(\left(2 - \dfrac{1}{2}\dfrac{a_0}{a}\right) \ln \dfrac{a + \sqrt{\dfrac{aa_0}{2}}}{a - \sqrt{\dfrac{aa_0}{2}}} - 1 \right) \right. \\ \left. - \sum_{C,n=4}^{4} \dfrac{(Z-n)e^2}{8\pi\varepsilon_0} \left(\dfrac{1}{r_5} - \dfrac{1}{r_6} \right) - \sum_{N,n=4}^{5} \dfrac{(Z-n)e^2}{8\pi\varepsilon_0} \left(\dfrac{1}{r_6} - \dfrac{1}{r_7} \right) \right) \\ \left(1 + \sqrt{\dfrac{2\hbar \sqrt{\dfrac{e^2}{4\pi\varepsilon_o a^3}}}{m_e c^2}} \right) + \dfrac{1}{2}\hbar\sqrt{\dfrac{k}{\mu}} \end{array} \right\} \\ &= -33.52149\ eV - 0.17684\ eV + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \end{aligned} \tag{13.859}$$

From Eqs. (13.856-13.859), the total energy of the CN MO is:

$$\begin{aligned} E_{T+osc}(CN) &= -33.52149\ eV + \bar{E}_{osc}(CN) \\ &= -33.52149\ eV - 0.17684\ eV + \frac{1}{2}(0.25647\ eV) \\ &= -33.56970\ eV \end{aligned} \tag{13.860}$$

where the experimental ω_e was used for the $\hbar\sqrt{\dfrac{k}{\mu}}$ term.

The CN bond dissociation energy, $E_D(CN)$, is given by the difference between the sum of the energies of the C and N atoms and $E_{T+osc}(CN)$:

$$E_D(CN) = E(C) + E(N) - E_{T+osc}(CN) \tag{13.861}$$

where the energy of a carbon atom is [6]:

$$E(C) = -11.26030\ eV \tag{13.862}$$

and the energy of a nitrogen atom is [6]:

$$E(N) = -14.53414\ eV \tag{13.863}$$

Thus, the CN bond dissociation energy, $E_D(CN)$, given by Eqs. (13.860-13.863) is:

$$\begin{aligned} E_D(CN) &= -(11.26030\ eV + 14.53414\ eV) - E_{T+osc}(CN) \\ &= -25.79444\ eV - (-33.56970\ eV) \\ &= 7.77526\ eV \end{aligned} \tag{13.864}$$

The experimental CN bond dissociation energy is [50]:

$$E_{D298}(CN) = 7.7731\ eV \tag{13.865}$$

The results of the determination of bond parameters of CN are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

CARBON MONOXIDE MOLECULE

The carbon monoxide molecule can be formed by the reaction of carbon and oxygen atoms:

$$C + O \rightarrow CO \tag{13.866}$$

The bond in the carbon monoxide molecule comprises a double bond, a H_2-type molecular orbital (MO) with four paired electrons. The force balance equation and radius r_6 of the $2p$ shell of C is derived in the Six-Electron Atoms section. The force balance equation and radius r_8 of the $2p$ shell of O is derived in the Eight-Electron Atoms section. With the formation of the H_2-type MO by the contribution of two $2p$ electrons from each of the C and O atoms, a diamagnetic force arises between the remaining outer shell atomic electrons, the $2s$ electrons of C and the $2p$ electrons of O, and the H_2-type MO. This force from C and O causes the H_2-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the factor of two increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining $O2p$ electrons decrease the radius of the corresponding shell such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of CO is $C1s^2O1s^2C2s^2O2s^2O2p^2\sigma_{C,O}^4$ where σ designates the H_2-type MO, and the orbital arrangement is:

σ state

$\underline{\uparrow\downarrow}\ \underline{\uparrow\downarrow}$

2p state

$\underline{\uparrow\downarrow}$

0

2s state

$\underline{\uparrow\downarrow}\qquad\underline{\uparrow\downarrow}$ (13.867)

1s state

$\underline{\uparrow\downarrow}\qquad\underline{\uparrow\downarrow}$

$C\qquad O$

Carbon monoxide is predicted to be diamagnetic in agreement with observations [42].

FORCE BALANCE OF THE $2p$ SHELL OF THE OXYGEN ATOM OF THE CARBON MONOXIDE MOLECULE

For the O atom, force balance for the outermost $2p$ electron of CO (electron 6) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 6 and the other $2p$ electron as well as the $2s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Eight-Electron Atoms section. The central Coulomb force on the outer-most $2p$ shell electron of CO (electron 6) due to the nucleus and the inner five electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele} = \frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2}\mathbf{i}_r \tag{13.868}$$

for $r > r_5$. The $2p$ shell possesses a +2 external electric field given by Eq. (10.92) for $r > r_6$. The energy is minimized with conservation of angular momentum. This condition is met when the diamagnetic force, $\mathbf{F}_{diamagnetic}$, of Eq. (10.82) due to the p-orbital contribution is given by:

$$\begin{aligned}\mathbf{F}_{diamagnetic} &= -\left(\frac{1}{3}\right)\frac{\hbar^2}{4m_e r_6^2 r_3}\sqrt{s(s+1)}\mathbf{i}_r \\ &= -\frac{\hbar^2}{12m_e r_6^2 r_3}\sqrt{\frac{3}{4}}\mathbf{i}_r\end{aligned} \tag{13.869}$$

And, $\mathbf{F}_{mag\ 2}$ corresponding to the conserved spin and orbital angular momentum given by Eq. (10.157) is:

$$\mathbf{F}_{mag\ 2} = \frac{1}{Z}\frac{2\hbar^2}{m_e r_6^2 r_3}\sqrt{s(s+1)}\mathbf{i}_r \tag{13.870}$$

The electric field external to the $2p$ shell given by Eq. (10.92) for $r > r_6$ gives rise to a second diamagnetic force, $\mathbf{F}_{diamagnetic\ 2}$, given by Eq. (10.93). $\mathbf{F}_{diamagnetic\ 2}$ due to the binding of the p-orbital electron having an electric field of +2 outside of its radius is:

$$\mathbf{F}_{diamagnetic\ 2} = -\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{m_e r_6^4}10\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.871}$$

In addition, the contribution of two $2p$ electrons in the formation of the σ molecular orbital (MO) gives rise to a paramagnetic force on the remaining paired $2p$ electrons. The force $\mathbf{F}_{mag\ 3}$ is given by Eq. (13.625) wherein the radius is r_6:

$$\mathbf{F}_{mag\ 3} = \frac{\hbar^2}{4m_e r_6^3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.872}$$

The radius of the $2p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.868)) and diamagnetic (Eqs. (13.869) and (13.871)), and paramagnetic (Eqs. (13.870) and (13.872)) forces as follows:

$$\frac{m_e v_6^2}{r_6} = \left(\begin{array}{l}\dfrac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2} - \dfrac{\hbar^2}{12m_e r_6^2 r_3}\sqrt{s(s+1)} + \dfrac{2\hbar^2}{Zm_e r_6^2 r_3}\sqrt{s(s+1)} \\ -\left[\dfrac{Z-6}{Z-5}\right]\left(1-\dfrac{\sqrt{2}}{2}\right)\dfrac{r_3\hbar^2}{r_6^4 m_e}10\sqrt{s(s+1)} + \dfrac{\hbar^2}{4m_e r_6^3}\sqrt{s(s+1)}\end{array}\right) \tag{13.873}$$

Substitution of $v_6 = \dfrac{\hbar}{m_e r_6}$ (Eq. (1.35)) and $s = \dfrac{1}{2}$ into Eq. (13.873) gives:

$$\frac{\hbar^2}{m_e r_6^3} - \frac{\hbar^2}{4m_e r_6^3}\sqrt{\frac{3}{4}} = \frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2} - \frac{\hbar^2}{12m_e r_6^2 r_3}\sqrt{\frac{3}{4}} + \frac{2\hbar^2}{Zm_e r_6^2 r_3}\sqrt{\frac{3}{4}} - \left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_6^4 m_e}10\sqrt{\frac{3}{4}} \tag{13.874}$$

The quadratic equation corresponding to Eq. (13.874) is

$$r_6^2 - \frac{\dfrac{\hbar^2}{m_e}\left(1-\dfrac{\sqrt{3}}{8}\right)}{\left(\dfrac{(Z-5)e^2}{4\pi\varepsilon_0} - \left(\dfrac{1}{12}-\dfrac{2}{Z}\right)\dfrac{\hbar^2}{m_e r_3}\sqrt{\dfrac{3}{4}}\right)}r_6 - \frac{\dfrac{\hbar^2}{m_e}\left[\dfrac{Z-6}{Z-5}\right]\left(1-\dfrac{\sqrt{2}}{2}\right)r_3 10\sqrt{\dfrac{3}{4}}}{\left(\dfrac{(Z-5)e^2}{4\pi\varepsilon_0} - \left(\dfrac{1}{12}-\dfrac{2}{Z}\right)\dfrac{\hbar^2}{m_e r_3}\sqrt{\dfrac{3}{4}}\right)} = 0 \tag{13.875}$$

The solution of Eq. (13.875) using the quadratic formula is:

$$r_6 = \frac{\dfrac{a_0\left(1-\dfrac{\sqrt{3}}{8}\right)}{\left((Z-5) - \left(\dfrac{1}{12}-\dfrac{2}{Z}\right)\dfrac{\sqrt{3}}{2r_3}\right)} \pm a_0\sqrt{\left(\dfrac{1-\dfrac{\sqrt{3}}{8}}{\left((Z-5) - \left(\dfrac{1}{12}-\dfrac{2}{Z}\right)\dfrac{\sqrt{3}}{2r_3}\right)}\right)^2 + \dfrac{20\sqrt{3}\left(\left[\dfrac{Z-6}{Z-5}\right]\left(1-\dfrac{\sqrt{2}}{2}\right)r_3\right)}{\left((Z-5) - \left(\dfrac{1}{12}-\dfrac{2}{Z}\right)\dfrac{\sqrt{3}}{2r_3}\right)}}}{2}, \; r_3 \text{ in units of } a_0 \tag{13.876}$$

The positive root of Eq. (13.876) must be taken in order that $r_6 > 0$. Substitution of $\dfrac{r_3}{a_0} = 0.59020$ (Eq. (10.62) with $Z = 8$) into Eq. (13.876) gives:

$$r_6 = 0.68835a_0 \tag{13.877}$$

ENERGIES OF THE $2s$ AND $2p$ SHELLS OF THE CARBON ATOM AND THE $2p$ SHELL OF THE OXYGEN ATOM OF THE CARBON MONOXIDE MOLECULE

With the formation of the H_2-type MO by the contribution of two $2p$ electrons from the C atom, the remaining outer-shell atomic electrons comprise the $2s$ electrons, which are unchanged by bonding with oxygen. However, the total energy of the CO molecule, which is subtracted from the sum of the energies of the carbon and oxygen atoms to determine the bond energy, is increased by the ionization energies of C^+ and O^+ given by Eqs. (10.113-10.114) and (10.152-10.153), respectively. Experimentally, the energies are [6] :

$$E(ionization;\ C^+) = 24.38332\ eV \tag{13.878}$$

$$E(ionization;\ O^+) = 35.11730\ eV \tag{13.879}$$

In addition, the central forces on the $2p$ shell of the O atom are increased with the formation of the σ MO, which reduces the shell's radius and increases its total energy. The Coulombic energy terms of the total energy of the O atom at the new radius are calculated and added to the ionization energies of C^+ and O^+, and the energy of the σ MO to give the total energy of CO. Then, the bond energy is determined from the total CO energy.

The radius r_8 of the oxygen atom before bonding is given by Eq. (10.162):

$$r_8 = a_0 \tag{13.880}$$

Using the initial radius r_8 of the O atom and the final radius r_6 of the $O2p$ shell (Eq. (13.877)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_T(O,2p)$ of the Coulombic energy change of the $O2p$ electrons of the O atom is determined using Eq. (10.102):

$$E_T(O,2p) = -\sum_{n=4}^{5} \frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_6}-\frac{1}{r_8}\right) = -(13.60580\ eV)(0.45275)(3+4) = -43.11996\ eV \tag{13.881}$$

FORCE BALANCE OF THE σ MO OF THE CARBON MONOXIDE MOLECULE

The force balance can be considered due to a second pair of two electrons binding to a molecular ion having $+2e$ at each focus and a first bound pair. Then, the forces are the same as those of a molecule ion having $+e$ at each focus. The diamagnetic force $\mathbf{F}_{diamagneticMO1}$ for the σ-MO of the CO molecule due to the two paired electrons in each of the $C2s$ and $O2p$ shells is given by Eq. (13.633) with $n_e = 2$:

$$\mathbf{F}_{diamagneticMO1} = \frac{\hbar^2}{2m_e a^2 b^2} D\mathbf{i}_\xi \tag{13.882}$$

The force $\mathbf{F}_{diamagneticMO2}$ is given by Eqs. (13.634) and (13.835) as the sum of the contributions due to carbon with $Z = Z_1$ and oxygen with $Z = Z_2$. $\mathbf{F}_{diamagneticMO1}$ for CO with $|L_i| = \hbar$ is:

$$\mathbf{F}_{diamagneticMO2} = \left(\frac{1}{Z_1}+\frac{1}{Z_2}\right)\frac{\hbar^2}{2m_e a^2 b^2} D\mathbf{i}_\xi \tag{13.883}$$

The force balance equation for the σ-MO of the carbon monoxide molecule given by Eqs. (11.200), (13.633-13.634), and (13.882-13.883) is:

$$\frac{\hbar^2}{m_e a^2 b^2} D = \frac{e^2}{8\pi\varepsilon_0 ab^2} D + \frac{\hbar^2}{2m_e a^2 b^2} D - \left(1+\left(\frac{1}{Z_1}+\frac{1}{Z_2}\right)\right)\frac{\hbar^2}{2m_e a^2 b^2} D \tag{13.884}$$

$$\frac{\hbar^2}{m_e a^2 b^2} D = \frac{e^2}{8\pi\varepsilon_0 ab^2} D - \left(\frac{1}{Z_1}+\frac{1}{Z_2}\right)\frac{\hbar^2}{2m_e a^2 b^2} D \tag{13.885}$$

$$\left(2+\frac{1}{Z_1}+\frac{1}{Z_2}\right)\frac{\hbar^2}{2m_e a^2 b^2} D = \frac{e^2}{8\pi\varepsilon_0 ab^2} D \tag{13.886}$$

$$a = \left(2+\frac{1}{Z_1}+\frac{1}{Z_2}\right)a_0 \tag{13.887}$$

Substitution of $Z_1 = 6$ and $Z_2 = 8$ into Eq. (13.887) gives:

$$a = 2.29167 a_0 = 1.21270\ X\ 10^{-10}\ m \tag{13.888}$$

Substitution of Eq. (13.888) into Eq. (11.79) is:

$$c' = 1.07044a_0 = 5.66450\ X\ 10^{-11}\ m \tag{13.889}$$

The internuclear distance given by multiplying Eq. (13.889) by two is:

$$2c' = 2.14087a_0 = 1.13290\ X\ 10^{-10}\ m \tag{13.890}$$

The experimental bond distance is [28]:

$$2c' = 1.12823\ X\ 10^{-10}\ m \tag{13.891}$$

Substitution of Eqs. (13.888-13.889) into Eq. (11.80) is:

$$b = c = 2.02630a_0 = 1.07227\ X\ 10^{-10}\ m \tag{13.892}$$

Substitution of Eqs. (13.888-13.889) into Eq. (11.67) is:

$$e = 0.46710 \tag{13.893}$$

Using the electron configuration of CO (Eq. (13.867)), the radii of the $C1s = 0.17113a_0$ (Eq. (10.51)), $C2s = 0.84317a_0$ (Eq. (10.62)), $O1s = 0.12739a_0$ (Eq. (10.51)), $O2s = 0.59020a_0$ (Eq. (10.62)), and $O2p = 0.68835a_0$ (Eq. (13.877)) shells and the parameters of the σ MO of CO given by Eqs. (13.3-13.4), (13.888-13.890), and (13.892-13.893), the dimensional diagram and charge-density of the CO MO are shown in Figures 13.24 and 13.25, respectively.

Figure 13.24. The cross section of the CO MO showing the axes, σ MO (H_2-type ellipsoidal MO) with four paired electrons, with the C $1s$ and $2s$ atomic orbitals (AOs) and the O $1s$, $2s$, and $2p$ AOs. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, r_4: radius of the $C2s$ shell having two paired electrons, r_6: radius of the $O2p$ shell having two paired electrons.

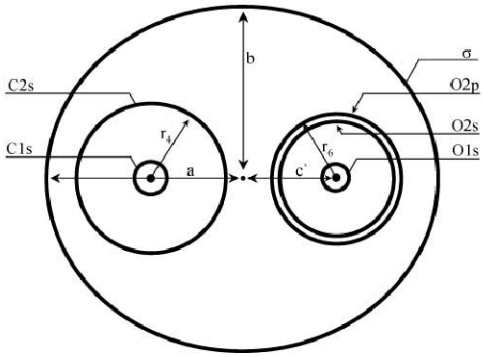

Figure 13.25. CO MO comprising the σ MO (H_2-type MO) with C and O atoms at the foci that have each donated two electrons to the σ MO. Consequently, the outer electrons of the carbon atom comprise the $C2s$ shell, and the $O2p$ shell has a smaller radius and a higher binding energy. (A) Color scale, translucent view of the charge-density of the CO MO. (B) Off-center cut-away view showing the complete inner most $O1s$ shell, and moving radially, the $O2s$ shell, the $O2p$ shell, and the σ prolate spheroidal MO that has the O atom as a focus. Moving radially from the carbon-atom focus, the complete inner most $C1s$ shell, the $C2s$ shell, and the σ prolate spheroidal MO are shown.

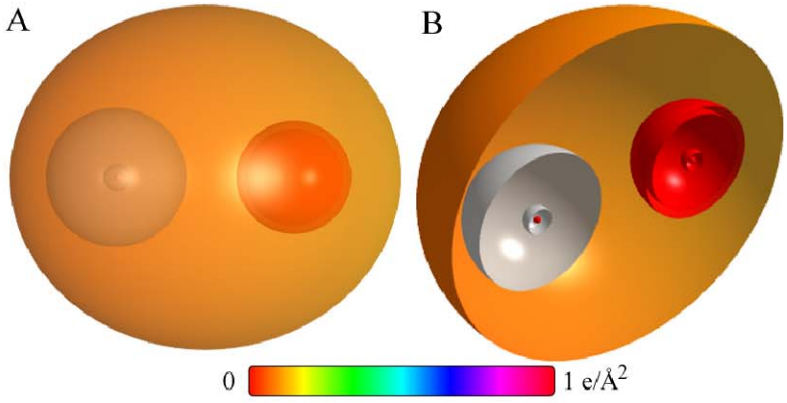

SUM OF THE ENERGIES OF THE σ MO AND THE AOs OF THE CARBON MONOXIDE MOLECULE

The energies of the CO σ MO are given by the substitution of the semiprincipal axes (Eqs. (13.888-13.889) and (13.892)) into the energy equations (Eqs. (11.207-11.212)) of H_2 except that the terms based on charge are multiplied by four and the kinetic energy term is multiplied by two due to the σ-MO double bond with two pairs of paired electrons:

$$V_e = 2^2 \frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} \ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -102.97635\ eV \tag{13.894}$$

$$V_p = 2^2 \frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 50.84210\ eV \tag{13.895}$$

$$T = 2\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}} \ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 11.23379\ eV \tag{13.896}$$

$$V_m = 2^2 \frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}} \ln \frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -11.23379\ eV \tag{13.897}$$

$$E_T = V_e + T + V_m + V_p \tag{13.898}$$

Substitution of Eqs. (11.79) and (13.894-13.897) into Eq. (13.898) gives:

$$E_T(CO,\sigma) = \frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2}}} \left(8\ln \frac{a+\sqrt{\frac{aa_0}{2}}}{a-\sqrt{\frac{aa_0}{2}}} - 4 \right) = -52.13425\ eV \tag{13.899}$$

where $E_T(CO,\sigma)$ is the total energy of the σ MO of CO. The total energy of CO, $E_T(CO)$, is given by the sum of $E(ionization;\ C^+)$, the energy of the second electron of carbon (Eq. (13.878)) donated to the double bond, $E(ionization;\ O^+)$, the energy of the second electron of oxygen (Eq. (13.879)) donated to the double bond, $E_T(O,2p)$, the $O2p$ AO contribution due to the decrease in radius with bond formation (Eq. (13.881)), and $E_T(CO,\sigma)$, the σ MO contribution given by Eq. (13.899):

$$\begin{aligned} E_T(CO) &= E(ionization;\ C^+) + E(ionization;\ O^+) + E_T(O,2p) + E_T(CO,\sigma) \\ &= 24.38332\ eV + 35.11730\ eV - 43.11996\ eV - 52.13425\ eV \\ &= -35.75359\ eV \end{aligned} \tag{13.900}$$

VIBRATION OF *CO*

The vibrational energy levels of CO may be solved by determining the Morse potential curve from the energy relationships for the transition from a C atom and O atom whose parameters are given by Eqs. (10.115-10.123) and (10.154-10.163), respectively, to a C atom whose parameter r_4 is given by Eq. (10.61), an O atom whose parameter r_6 is given by Eq. (13.877), and the σ MO whose parameters are given by Eqs. (13.888-13.890) and (13.892-13.893). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K&P) [15] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

THE DOPPLER ENERGY TERMS OF THE CARBON MONOXIDE MOLECULE

The equations of the radiation reaction force of carbon monoxide are the same as those of H_2 with the substitution of the CO parameters except that there is a factor of four increase in the central force in Eq. (11.231) due to the double bond. Using Eqs. (11.231-11.233), the angular frequency of the reentrant oscillation in the transition state is

$$\omega = \sqrt{\frac{\frac{4e^2}{4\pi\varepsilon_0 a^3}}{m_e}} = 2.38335\ X\ 10^{16}\ rad/s \tag{13.901}$$

where a is given by Eq. (13.888). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\begin{aligned} \bar{E}_K &= \hbar\omega = \hbar 2.38335\ X\ 10^{16}\ rad/s \\ &= 15.68762\ eV \end{aligned} \tag{13.902}$$

In Eq. (11.181), substitution of $E_T(CO)$ for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (13.902) for $\bar{E}_K$ gives the Doppler energy of the electrons of the reentrant orbit:

$$\begin{aligned} \bar{E}_D &\cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}} \\ &= -35.75359\ eV\sqrt{\frac{2e(15.68762\ eV)}{m_e c^2}} = -0.28016\ eV \end{aligned} \tag{13.903}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the CO MO due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (13.903) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy. Using the experimental CO ω_e of 2169.81 cm^{-1} $(0.26902\ eV)$ [28] for $\bar{E}_{Kvib}$ of the transition state, $\bar{E}'_{osc}(CO)$ per bond is:

$$\bar{E}'_{osc}(CO) = \bar{E}_D + \bar{E}_{Kvib} = \bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{13.904}$$

$$\bar{E}'_{osc}(CO) = -0.28016\ eV + \frac{1}{2}(0.26902\ eV) = -0.14564\ eV \tag{13.905}$$

Since the σ MO bond is a double bond with twice a many electrons as a single bond, $\bar{E}'_{osc}(CO)$ is multiplied by two to give:

$$\bar{E}_{osc}(CO) = -0.29129\ eV \tag{13.906}$$

TOTAL AND BOND ENERGIES OF THE CARBON MONOXIDE MOLECULE

$E_{T+osc}(CO)$, the total energy of CO including the Doppler term, is given by the sum of $E_T(CO)$ (Eq. (13.900)) and $\bar{E}_{osc}(CO)$ given by Eq. (13.906):

$$\begin{aligned} E_{T+osc}(CO) &= \begin{pmatrix} V_e + T + V_m + V_p + E(ionization;\ C^+) \\ +E(ionization;\ O^+) + E_T(O,2p) + \bar{E}_{osc}(CO) \end{pmatrix} \\ &= \begin{pmatrix} E_T(CO,\sigma) + E(ionization;\ C^+) + E(ionization;\ O^+) \\ +E_T(O,2p) + \bar{E}_{osc}(CO) \end{pmatrix} \\ &= E_T(CO) + \bar{E}_{osc}(CO) \end{aligned} \tag{13.907}$$

$$\begin{aligned} E_{T+osc}(CO) = \Bigg\{ & \begin{pmatrix} \dfrac{-e^2}{8\pi\varepsilon_0\sqrt{\dfrac{aa_0}{2}}}\left(8\ln\dfrac{a+\sqrt{\dfrac{aa_0}{2}}}{a-\sqrt{\dfrac{aa_0}{2}}} - 4\right) + E\left(ionization;\ C^+\right) \\ +E\left(ionization;\ O^+\right) - \displaystyle\sum_{O,n=4}^{5} \dfrac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\dfrac{1}{r_6} - \dfrac{1}{r_8}\right) \end{pmatrix} \Bigg\} \\ & \begin{pmatrix} 1 + 2\sqrt{\dfrac{2\hbar\sqrt{\dfrac{4e^2}{4\pi\varepsilon_0 a^3}}}{m_e c^2}} \end{pmatrix} + 2\left(\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \\ = & -35.75359\ eV - 2(0.28016\ eV) + 2\left(\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \end{aligned} \tag{13.908}$$

From Eqs. (13.906-13.908), the total energy of the CO MO is:

$$\begin{aligned} E_{T+osc}(CO) &= -35.75359\ eV + \bar{E}_{osc}(CO) \\ &= -35.75359\ eV + (-0.29129\ eV) = -36.04488\ eV \end{aligned} \tag{13.909}$$

where the experimental ω_e was used for the $\hbar\sqrt{\frac{k}{\mu}}$ term.

The CO bond dissociation energy, $E_D(CO)$, is given by the difference between the sum of the energies of the C and O atoms and $E_{T+osc}(CO)$:

$$E_D(CO) = E(C) + E(O) - E_{T+osc}(CO) \tag{13.910}$$

where the energy of a carbon atom is [6]:

$$E(C) = -11.26030\ eV \tag{13.911}$$

and the energy of an oxygen atom is [6]:

$$E(O) = -13.61806\ eV \tag{13.912}$$

Thus, the CO bond dissociation energy, $E_D(CO)$, given by Eqs. (13.909-13.912) is:

$$\begin{aligned} E_D(CO) &= -(11.26030\ eV + 13.61806\ eV) - E_{T+osc}(CO) \\ &= -24.87836\ eV - (-36.04488\ eV) = 11.16652\ eV \end{aligned} \tag{13.913}$$

The experimental CO bond dissociation energy is [49]:

$$E_{D298}(CO) = 11.15696\ eV \tag{13.914}$$

The results of the determination of bond parameters of CO are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

NITRIC OXIDE RADICAL

The nitric oxide radical can be formed by the reaction of nitrogen and oxygen atoms:

$$N + O \rightarrow NO \tag{13.915}$$

The bond in the nitric oxide radical comprises a double bond, a H_2-type molecular orbital (MO) with four paired electrons. The force balance equation and radius r_7 of the $2p$ shell of N is derived in the Seven-Electron Atoms section. The force balance equation and radius r_8 of the $2p$ shell of O is derived in the Eight-Electron Atoms section. With the formation of the H_2-type MO by the contribution of two $2p$ electrons from each of the N and O atoms, a diamagnetic force arises between the remaining outer shell atomic electrons, the $2s$ and $2p$ electrons of N and O, and the H_2-type MO. This force from N and O causes the H_2-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the factor of two increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining N and O electrons decrease the radii of the corresponding shells such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of NO is $N1s^2O1s^2N2s^2O2s^2N2p^1O2p^2\sigma_{N,O}^4$ where σ designates the H_2-type MO, and the orbital arrangement is:

σ state

$\underline{\uparrow\downarrow}\ \underline{\uparrow\downarrow}$

2p state

$\underline{\uparrow}\quad\quad\underline{\uparrow\downarrow}$

0 0

2s state

$\underline{\uparrow\downarrow}\quad\quad\underline{\uparrow\downarrow}$ (13.916)

1s state

$\underline{\uparrow\downarrow}\quad\quad\underline{\uparrow\downarrow}$

$N\quad\quad O$

Nitric oxide is predicted to be weakly paramagnetic in agreement with observations [42].

FORCE BALANCE OF THE $2p$ SHELL OF THE NITROGEN ATOM OF THE NITRIC OXIDE RADICAL

For the N atom, force balance for the outermost $2p$ electron of NO (electron 5) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 5 and the $2s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Seven-Electron Atoms section. The central Coulomb force on the outer-most $2p$ shell electron of NO (electron 5) due to the nucleus and the inner four electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele} = \frac{(Z-4)e^2}{4\pi\varepsilon_0 r_5^2}\mathbf{i}_\mathbf{r} \tag{13.917}$$

for $r > r_4$. The $2p$ shell possess a +2 external electric field given by Eq. (10.92) for $r > r_5$. The energy is minimized with conservation of angular momentum. This condition is met when the magnetic forces of N in NO are the same as those of N in the nitrogen molecule with r_5 replacing r_6 and with an increase of the central field by an integer. The diamagnetic force, $\mathbf{F}_{diamagnetic}$, of Eq. (10.82) due to the p-orbital contribution is given by Eq. (13.622) with r_5 replacing r_6:

$$\mathbf{F}_{diamagnetic} = -\left(\frac{1}{3}\right)\frac{\hbar^2}{4m_e r_5^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} = -\frac{\hbar^2}{12m_e r_5^2 r_3}\sqrt{\frac{3}{4}}\mathbf{i}_\mathbf{r} \tag{13.918}$$

And, $\mathbf{F}_{mag\ 2}$ corresponding to the conserved orbital angular momentum of the three orbitals is also the same as that of N_2 given by Eq. (13.623) with r_5 replacing r_6:

$$\mathbf{F}_{mag\ 2} = \frac{1}{Z}\frac{3\hbar^2}{m_e r_5^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.919}$$

The electric field external to the $2p$ shell given by Eq. (10.92) for $r > r_5$ gives rise to a second diamagnetic force, $\mathbf{F}_{diamagnetic\ 2}$, given by Eq. (10.93). $\mathbf{F}_{diamagnetic\ 2}$ due to the binding of the p-orbital electron having an electric field of +2 outside of its radius follows from Eq. (13.624).

$$\mathbf{F}_{diamagnetic\ 2} = -\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{m_e r_5^4}10\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.920}$$

In addition to the N forces $\mathbf{F}_{ele}$, $\mathbf{F}_{diamagnetic}$, $\mathbf{F}_{mag\ 2}$, and $\mathbf{F}_{diamagnetic\ 2}$ of NO being the same as N_2 given by Eqs. (13.621-13.624), respectively, $\mathbf{F}_{ele}$, $\mathbf{F}_{mag\ 2}$, and $\mathbf{F}_{diamagnetic\ 2}$ are also the same as those of CN (Eqs. (13.820) and (13.822-13.823)). In the N_2 and CN cases, the contribution of a $2p$ electron from the N atom in the formation of the σ MO gives rise to an additional paramagnetic force on the remaining two $2p$ electrons that pair. However, the force, $\mathbf{F}_{mag\ 3}$, is absent in NO since the single outer electron is unpaired.

The radius of the $2p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.917)) and diamagnetic (Eqs. (13.918) and (13.920)), and paramagnetic (Eq. (13.919)) forces as follows:

$$\frac{m_e v_5^2}{r_5} = \left(\begin{array}{l}\frac{(Z-4)e^2}{4\pi\varepsilon_0 r_5^2} - \frac{\hbar^2}{12 m_e r_5^2 r_3}\sqrt{s(s+1)} + \frac{3\hbar^2}{Z m_e r_5^2 r_3}\sqrt{s(s+1)} \\ -\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_5^4 m_e}10\sqrt{s(s+1)}\end{array}\right) \tag{13.921}$$

Substitution of $v_5 = \frac{\hbar}{m_e r_5}$ (Eq. (1.35)) and $s = \frac{1}{2}$ into Eq. (13.921) gives:

$$\frac{\hbar^2}{m_e r_5^3} = \frac{(Z-4)e^2}{4\pi\varepsilon_0 r_5^2} - \frac{\hbar^2}{12 m_e r_5^2 r_3}\sqrt{\frac{3}{4}} + \frac{3\hbar^2}{Z m_e r_5^2 r_3}\sqrt{\frac{3}{4}} - \left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_5^4 m_e}10\sqrt{\frac{3}{4}} \tag{13.922}$$

The quadratic equation corresponding to Eq. (13.922) is

$$r_5^2 - \frac{\frac{\hbar^2}{m_e}}{\left(\frac{(Z-4)e^2}{4\pi\varepsilon_0} - \left(\frac{1}{12}-\frac{3}{Z}\right)\frac{\hbar^2}{m_e r_3}\sqrt{\frac{3}{4}}\right)}r_5 - \frac{\frac{\hbar^2}{m_e}\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3 10\sqrt{\frac{3}{4}}}{\left(\frac{(Z-4)e^2}{4\pi\varepsilon_0} - \left(\frac{1}{12}-\frac{3}{Z}\right)\frac{\hbar^2}{m_e r_3}\sqrt{\frac{3}{4}}\right)} = 0 \tag{13.923}$$

The solution of Eq. (13.923) using the quadratic formula is:

$$r_5 = \frac{\frac{a_0}{\left((Z-4) - \left(\frac{1}{12}-\frac{3}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)} \pm a_0\sqrt{\left(\frac{1}{\left((Z-4) - \left(\frac{1}{12}-\frac{3}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}\right)^2 + \frac{20\sqrt{3}\left(\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3\right)}{\left((Z-4) - \left(\frac{1}{12}-\frac{3}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}}}{2}, \; r_3 \text{ in units of } a_0 \tag{13.924}$$

The positive root of Eq. (13.924) must be taken in order that $r_5 > 0$. Substitution of $\frac{r_3}{a_0} = 0.69385$ (Eq. (10.62) with $Z = 7$) into Eq. (13.924) gives:

$$r_5 = 0.74841 a_0 \tag{13.925}$$

FORCE BALANCE OF THE $2p$ SHELL OF THE OXYGEN ATOM OF THE NITRIC OXIDE RADICAL

For the O atom, force balance for the outermost $2p$ electron of NO (electron 6) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 6 and the other $2p$ electron as well as the $2s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Eight-Electron Atoms section. The central Coulomb force on the outer-most $2p$ shell electron of NO (electron 6) due to the nucleus and the inner five electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele} = \frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2}\mathbf{i}_\mathbf{r} \tag{13.926}$$

for $r > r_5$. The $2p$ shell possess an external electric field of +2 given by Eq. (10.92) for $r > r_6$. The energy is minimized with conservation of angular momentum. This condition is met when the diamagnetic force, $\mathbf{F}_{diamagnetic}$, of Eq. (10.82) due to the p-orbital contribution is given by:

$$\begin{aligned}\mathbf{F}_{diamagnetic} &= -\left(\frac{2}{3}\right)\frac{\hbar^2}{4m_e r_6^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \\ &= -\frac{2\hbar^2}{12m_e r_6^2 r_3}\sqrt{\frac{3}{4}}\mathbf{i}_\mathbf{r}\end{aligned} \tag{13.927}$$

And, $\mathbf{F}_{mag\ 2}$ corresponding to the conserved spin and orbital angular momentum given by Eqs. (10.157) and (13.670) is:

$$\mathbf{F}_{mag\ 2} = \frac{1}{Z}\frac{2\hbar^2}{m_e r_6^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.928}$$

The electric field external to the $2p$ shell given by Eq. (10.92) for $r > r_6$ gives rise to a second diamagnetic force, $\mathbf{F}_{diamagnetic\ 2}$, given by Eq. (10.93). $\mathbf{F}_{diamagnetic\ 2}$ due to the binding of the p-orbital electron having an electric field of +2 outside of its radius is:

$$\mathbf{F}_{diamagnetic\ 2} = -\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{m_e r_6^4}10\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.929}$$

In addition, the contribution of two $2p$ electrons in the formation of the σ MO gives rise to a paramagnetic force on the remaining paired $2p$ electrons. The force $\mathbf{F}_{mag\ 3}$ is given by Eq. (13.625) wherein the radius is r_6:

$$\mathbf{F}_{mag\ 3} = \frac{\hbar^2}{4m_e r_6^3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{13.930}$$

The radius of the $2p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (13.926)) and diamagnetic (Eqs. (13.927) and (13.929)), and paramagnetic (Eqs. (13.928) and (13.930)) forces as follows:

$$\frac{m_e v_6^2}{r_6} = \left(\begin{array}{l}\frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2} - \frac{2\hbar^2}{12m_e r_6^2 r_3}\sqrt{s(s+1)} + \frac{2\hbar^2}{Zm_e r_6^2 r_3}\sqrt{s(s+1)} \\ -\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_6^4 m_e}10\sqrt{s(s+1)} + \frac{\hbar^2}{4m_e r_6^3}\sqrt{s(s+1)}\end{array}\right) \tag{13.931}$$

Substitution of $v_6 = \frac{\hbar}{m_e r_6}$ (Eq. (1.35)) and $s = \frac{1}{2}$ into Eq. (13.931) gives:

$$\frac{\hbar^2}{m_e r_6^3} - \frac{\hbar^2}{4m_e r_6^3}\sqrt{\frac{3}{4}} = \frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2} - \frac{2\hbar^2}{12m_e r_6^2 r_3}\sqrt{\frac{3}{4}} + \frac{2\hbar^2}{Zm_e r_6^2 r_3}\sqrt{\frac{3}{4}} - \left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_6^4 m_e}10\sqrt{\frac{3}{4}} \tag{13.932}$$

The quadratic equation corresponding to Eq. (13.932) is:

$$r_6^2 - \frac{\frac{\hbar^2}{m_e}\left(1-\frac{\sqrt{3}}{8}\right)}{\left(\frac{(Z-5)e^2}{4\pi\varepsilon_0} - \left(\frac{2}{12}-\frac{2}{Z}\right)\frac{\hbar^2}{m_e r_3}\sqrt{\frac{3}{4}}\right)}r_6 - \frac{\frac{\hbar^2}{m_e}\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3 10\sqrt{\frac{3}{4}}}{\left(\frac{(Z-5)e^2}{4\pi\varepsilon_0} - \left(\frac{2}{12}-\frac{2}{Z}\right)\frac{\hbar^2}{m_e r_3}\sqrt{\frac{3}{4}}\right)} = 0 \tag{13.933}$$

The solution of Eq. (13.933) using the quadratic formula is:

$$r_6 = \frac{\dfrac{a_0\left(1-\dfrac{\sqrt{3}}{8}\right)}{\left((Z-5)-\left(\dfrac{2}{12}-\dfrac{2}{Z}\right)\dfrac{\sqrt{3}}{2r_3}\right)} \pm a_0\sqrt{\left(\dfrac{1-\dfrac{\sqrt{3}}{8}}{\left((Z-5)-\left(\dfrac{2}{12}-\dfrac{2}{Z}\right)\dfrac{\sqrt{3}}{2r_3}\right)}\right)^2 + \dfrac{20\sqrt{3}\left(\left[\dfrac{Z-6}{Z-5}\right]\left(1-\dfrac{\sqrt{2}}{2}\right)r_3\right)}{\left((Z-5)-\left(\dfrac{2}{12}-\dfrac{2}{Z}\right)\dfrac{\sqrt{3}}{2r_3}\right)}}}{2}, \; r_3 \text{ in units of } a_0 \tag{13.934}$$

The positive root of Eq. (13.934) must be taken in order that $r_6 > 0$. Substitution of $\frac{r_3}{a_0} = 0.59020$ (Eq. (10.62) with $Z = 8$) into Eq. (13.934) gives:

$$r_6 = 0.70460 a_0 \tag{13.935}$$

ENERGIES OF THE $2p$ SHELLS OF THE NITROGEN ATOM AND OXYGEN ATOM OF THE NITRIC OXIDE RADICAL

With the formation of the H_2-type MO by the contribution of two $2p$ electrons from each of the N and O atoms, the total energy of the NO molecule, which is subtracted from the sum of the energies of the nitrogen and oxygen atoms to determine the bond energy, is increased by the ionization energies of N^+ and O^+ given by Eqs. (10.132-10.133) and (10.152-10.153), respectively. Experimentally, the energies are [6] :

$$E(\textit{ionization};\ N^+) = 29.6013\ eV \tag{13.936}$$

$$E(\textit{ionization};\ O^+) = 35.11730\ eV \tag{13.937}$$

In addition, the central forces on the $2p$ shells of the N and O atoms are increased with the formation of the σ MO which reduces each shell's radius and increases its total energy. The Coulombic energy terms of the total energy of the N and O atoms at the new radii are calculated and added to the ionization energies of N^+ and O^+, and the energy of the σ MO to give the total energy of NO. Then, the bond energy is determined from the total NO energy.

The radius r_7 of the nitrogen atom before bonding is given by Eq. (10.142):

$$r_7 = 0.93084 a_0 \tag{13.938}$$

Using the initial radius r_7 of the N atom and the final radius r_5 of the $N2p$ shell (Eq. (13.925)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_T(N,2p)$ of the Coulombic energy change of the $N2p$ electrons of the N atom is determined using Eq. (10.102):

$$E_T(N,2p) = -\sum_{n=4}^{4}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_5}-\frac{1}{r_7}\right) = -(13.60580\ eV)(0.26186)(3) = -10.68853\ eV \tag{13.939}$$

The radius r_8 of the oxygen atom before bonding is given by Eq. (10.162):

$$r_8 = a_0 \tag{13.940}$$

Using the initial radius r_8 of the O atom and the final radius r_6 of the $O2p$ shell (Eq. (13.935)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_T(O,2p)$ of the Coulombic energy change of the $O2p$ electrons of the O atom is determined using Eq. (10.102):

$$E_T(O,2p) = -\sum_{n=4}^{5}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_6}-\frac{1}{r_8}\right) = -(13.60580\ eV)(0.41925)(3+4) = -39.92918\ eV \tag{13.941}$$

FORCE BALANCE OF THE σ MO OF THE NITRIC OXIDE RADICAL

The force balance can be considered due to a second pair of two electrons binding to a molecular ion having $+2e$ at each focus and a first bound pair. Then, the forces are the same as those of a molecule ion having $+e$ at each focus. The diamagnetic force $\mathbf{F}_{diamagneticMO1}$ for the σ-MO of the NO molecule due to the two paired electrons in the $O2p$ shell is given by Eq. (13.633) with: $n_e = 2$:

$$\mathbf{F}_{diamagneticMO1} = \frac{\hbar^2}{2m_e a^2 b^2} D\mathbf{i}_\xi \tag{13.942}$$

$\mathbf{F}_{diamagneticMO2}$ of the nitric oxide radical comprising nitrogen with charge $Z_1 = 7$ and $|L_1| = \hbar$ and $|L_2| = \sqrt{\frac{3}{4}}\hbar$ and oxygen with $Z_2 = 8$ and $|L_3| = \hbar$ is given by the corresponding sum of the contributions. Using Eq. (13.835), $\mathbf{F}_{diamagneticMO2}$ for NO is:

$$\mathbf{F}_{diamagneticMO2} = \left(\frac{1}{Z_1} + \frac{\sqrt{\frac{3}{4}}}{Z_1} + \frac{1}{Z_2} \right) \frac{\hbar^2}{2m_e a^2 b^2} D\mathbf{i}_\xi \tag{13.943}$$

The general force balance equation for the σ-MO of the nitric oxide radical given by Eqs. (11.200), (13.633-13.634), and (13.942-13.943) is the same as that of CN (Eq. (13.836)):

$$\frac{\hbar^2}{m_e a^2 b^2} D = \frac{e^2}{8\pi\varepsilon_0 a b^2} D + \frac{\hbar^2}{2m_e a^2 b^2} D - \left(1 + \frac{1}{Z_1} + \frac{\sqrt{\frac{3}{4}}}{Z_1} + \frac{1}{Z_2} \right) \frac{\hbar^2}{2m_e a^2 b^2} D \tag{13.944}$$

$$\frac{\hbar^2}{m_e a^2 b^2} D = \frac{e^2}{8\pi\varepsilon_0 a b^2} D - \left(\frac{1}{Z_1} + \frac{\sqrt{\frac{3}{4}}}{Z_1} + \frac{1}{Z_2} \right) \frac{\hbar^2}{2m_e a^2 b^2} D \tag{13.945}$$

$$\left(2 + \frac{1}{Z_1} + \frac{\sqrt{\frac{3}{4}}}{Z_1} + \frac{1}{Z_2} \right) \frac{\hbar^2}{2m_e a^2 b^2} D = \frac{e^2}{8\pi\varepsilon_0 a b^2} D \tag{13.946}$$

$$a = \left(2 + \frac{1}{Z_1} + \frac{\sqrt{\frac{3}{4}}}{Z_1} + \frac{1}{Z_2} \right) a_0 \tag{13.947}$$

Substitution of $Z_1 = 7$ and $Z_2 = 8$ into Eq. (13.947) gives:

$$a = 2.39158 a_0 = 1.26557\ X\ 10^{-10}\ m \tag{13.948}$$

Substitution of Eq. (13.948) into Eq. (11.79) is:

$$c' = 1.09352 a_0 = 5.78666\ X\ 10^{-11}\ m \tag{13.949}$$

The internuclear distance given by multiplying Eq. (13.949) by two is:

$$2c' = 2.18704 a_0 = 1.15733\ X\ 10^{-10}\ m \tag{13.950}$$

The experimental bond distance is [28]:

$$2c' = 1.15077\ X\ 10^{-10}\ m \tag{13.951}$$

Substitution of Eqs. (13.948-13.949) into Eq. (11.80) is:

$$b = c = 2.12693 a_0 = 1.12552\ X\ 10^{-10}\ m \tag{13.952}$$

Substitution of Eqs. (13.948-13.949) into Eq. (11.67) is:

$$e = 0.45724 \tag{13.953}$$

Using the electron configuration of NO (Eq. (13.916)), the radii of the $N1s = 0.14605 a_0$ (Eq. (10.51)), $N2s = 0.69385 a_0$ (Eq. (10.62)), $N2p = 0.74841 a_0$ (Eq. (13.925)), $O1s = 0.12739 a_0$ (Eq. (10.51)), $O2s = 0.59020 a_0$ (Eq. (10.62)), and $O2p = 0.70460 a_0$ (Eq. (13.935)) shells and the parameters of the σ MO of NO given by Eqs. (13.3-13.4), (13.948-13.950), and (13.952-13.953), the dimensional diagram and charge-density of the NO MO are shown in Figures 13.26 and 13.27, respectively.

Figure 13.26. The cross section of the NO MO showing the axes, σ MO (H_2-type ellipsoidal MO) with four paired electrons, with the N $1s$, $2s$, and $2p$ atomic orbitals (AOs) and the O $1s$, $2s$, and $2p$ AOs. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, r_5: radius of the $N2p$ shell having two paired electrons, r_6: radius of the $O2p$ shell having two paired electrons.

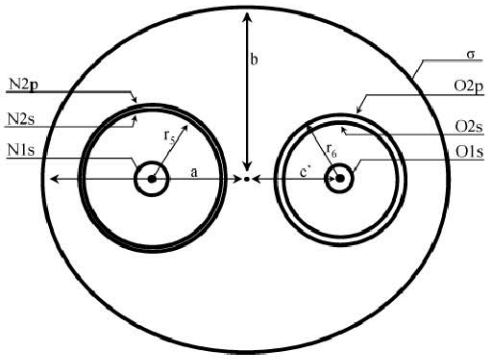

Figure 13.27. NO MO comprising the σ MO (H_2-type MO) with N and O atoms at the foci that have each donated two electrons to the σ MO and have smaller radii and higher binding energies as a consequence. (A) Color scale, translucent view of the charge-density of the NO MO. (B) Off-center cut-away view showing the complete inner most $N1s$ shell, and moving radially, the $N2s$ shell, the $N2p$ shell, and the σ prolate spheroidal MO that has the N atom as a focus. Moving radially from the oxygen-atom focus, the complete inner most $O1s$ shell, the $O2s$ shell, the $O2p$ shell, and the σ prolate spheroidal MO are shown.

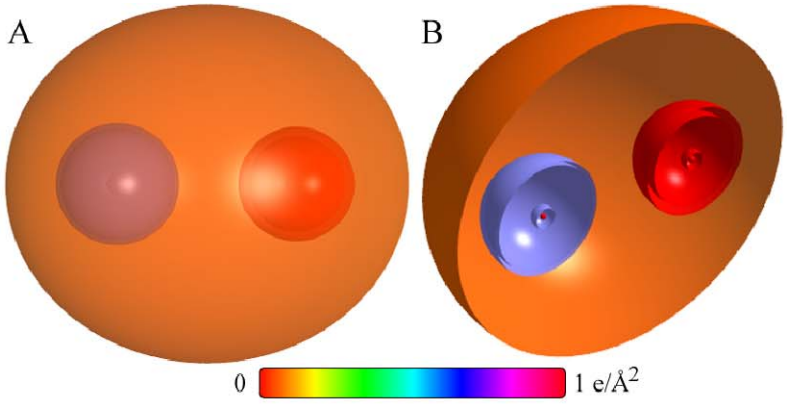

SUM OF THE ENERGIES OF THE σ MO AND THE AOs OF THE NITRIC OXIDE RADICAL

The energies of the NO σ MO are given by the substitution of the semiprincipal axes (Eqs. (13.948-13.949) and (13.952)) into the energy equations (Eqs. (11.207-11.212)) of H_2 except that the terms based on charge are multiplied by four and the kinetic energy term is multiplied by two due to the σ-MO double bond with two pairs of paired electrons:

$$V_e = 2^2 \frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} \ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -98.30623\ eV \tag{13.954}$$

$$V_p = 2^2 \frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 49.76880\ eV \tag{13.955}$$

$$T = 2\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}} \ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 10.27631\ eV \tag{13.956}$$

$$V_m = 2^2 \frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}} \ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -10.27631\ eV \tag{13.957}$$

$$E_T = V_e + T + V_m + V_p \tag{13.958}$$

Substitution of Eqs. (11.79) and (13.954-13.957) into Eq. (13.958) gives:

$$E_T(NO,\sigma) = \frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2}}}\left(8\ln\frac{a+\sqrt{\frac{aa_0}{2}}}{a-\sqrt{\frac{aa_0}{2}}} - 4\right) = -48.53743\ eV \tag{13.959}$$

where $E_T(NO,\sigma)$ is the total energy of the σ MO of NO. The total energy of NO, $E_T(NO)$, is given by the sum of $E(ionization; N^+)$, the energy of the second electron of nitrogen (Eq. (13.936)) donated to the double bond, $E(ionization; O^+)$, the energy of the second electron of oxygen (Eq. (13.937)) donated to the double bond, $E_T(N,2p)$, the $N2p$ AO contribution

due to the decrease in radius with bond formation (Eq. (13.939)), $E_T\left(O,2p\right)$, the $O2p$ AO contribution due to the decrease in radius with bond formation (Eq. (13.941)), and $E_T\left(NO,\sigma\right)$, the σ MO contribution given by Eq. (13.959).

$$E_T\left(NO\right)=\begin{pmatrix}E(ionization;\ N^+)+E(ionization;\ O^+)\\+E_T\left(N,2p\right)+E_T\left(O,2p\right)+E_T\left(NO,\sigma\right)\end{pmatrix}=\begin{pmatrix}29.6013\ eV+35.11730\ eV\\-10.68853\ eV-39.92918\ eV-48.53743\ eV\end{pmatrix}$$
$$=-34.43653\ eV \tag{13.960}$$

VIBRATION OF *NO*

The vibrational energy levels of NO may be solved by determining the Morse potential curve from the energy relationships for the transition from a N atom and O atom whose parameters are given by Eqs. (10.134-10.143) and (10.154-10.163), respectively, to a N atom whose parameter r_5 is given by Eq. (13.925), an O atom whose parameter r_6 is given by Eq. (13.935), and the σ MO whose parameters are given by Eqs. (13.948-13.950) and (13.952-13.953). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K&P) [15] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

THE DOPPLER ENERGY TERMS OF THE NITRIC OXIDE RADICAL

The equations of the radiation reaction force of nitric oxide are the same as those of H_2 with the substitution of the NO parameters except that there is a factor of four increase in the central force in Eq. (11.231) due to the double bond. Using Eqs. (11.231-11.233) and (13.901), the angular frequency of the reentrant oscillation in the transition state is

$$\omega=\sqrt{\frac{\frac{4e^2}{4\pi\varepsilon_0 a^3}}{m_e}}=2.23557\ X\ 10^{16}\ rad/s \tag{13.961}$$

where a is given by Eq. (13.948). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)):

$$\bar{E}_K=\hbar\omega=\hbar 2.23557\ X\ 10^{16}\ rad/s=14.71493\ eV \tag{13.962}$$

In Eq. (11.181), substitution of $E_T\left(NO\right)$ for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (13.962) for $\bar{E}_K$ gives the Doppler energy of the electrons of the reentrant orbit:

$$\bar{E}_D\cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}}=-34.43653\ eV\sqrt{\frac{2e\left(14.71493\ eV\right)}{m_e c^2}}=-0.26134\ eV \tag{13.963}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the NO MO due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (13.963) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy. Using the experimental NO ω_e of 1904.20 cm^{-1} $\left(0.23609\ eV\right)$ [28] for $\bar{E}_{Kvib}$ of the transition state, $\bar{E}'_{osc}\left(NO\right)$ per bond is:

$$\bar{E}'_{osc}\left(NO\right)=\bar{E}_D+\bar{E}_{Kvib}=\bar{E}_D+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{13.964}$$

$$\bar{E}'_{osc}\left(NO\right)=-0.26134\ eV+\frac{1}{2}\left(0.23609\ eV\right)=-0.14329\ eV \tag{13.965}$$

Since the σ MO bond is a double bond with twice a many electrons as a single bond, $\bar{E}'_{osc}\left(NO\right)$ is multiplied by two to give:

$$\bar{E}_{osc}\left(NO\right)=-0.28658\ eV \tag{13.966}$$

TOTAL AND BOND ENERGIES OF THE NITRIC OXIDE RADICAL

$E_{T+osc}(NO)$, the total energy of NO including the Doppler term, is given by the sum of $E_T(NO)$ (Eq. (13.960)) and $\bar{E}_{osc}(NO)$ given by Eq. (13.966).

$$\begin{aligned} E_{T+osc}(NO) &= \begin{pmatrix} V_e + T + V_m + V_p + E(ionization;\ N^+) + E(ionization;\ O^+) \\ + E_T(N,2p) + E_T(O,2p) + \bar{E}_{osc}(NO) \end{pmatrix} \\ &= \begin{pmatrix} E_T(NO,\sigma) + E(ionization;\ N^+) + E(ionization;\ O^+) \\ + E_T(N,2p) + E_T(O,2p) + \bar{E}_{osc}(NO) \end{pmatrix} \\ &= E_T(NO) + \bar{E}_{osc}(NO) \end{aligned} \tag{13.967}$$

$$E_{T+osc}(NO) = \left\{ \begin{pmatrix} \dfrac{-e^2}{8\pi\varepsilon_0\sqrt{\dfrac{aa_0}{2}}} \left(8\ln\dfrac{a+\sqrt{\dfrac{aa_0}{2}}}{a-\sqrt{\dfrac{aa_0}{2}}} - 4 \right) \\ + E(ionization;\ N^+) + E(ionization;\ O^+) \\ - \sum_{N,n=4}^{4} \dfrac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\dfrac{1}{r_5} - \dfrac{1}{r_7}\right) - \sum_{O,n=4}^{5} \dfrac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\dfrac{1}{r_6} - \dfrac{1}{r_8}\right) \end{pmatrix} \right\} \\ \left(1 + 2\sqrt{\dfrac{2\hbar\sqrt{\dfrac{4e^2}{4\pi\varepsilon_0 a^3 m_e}}}{m_e c^2}} \right) + 2\left(\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \\ = -34.43653\ eV - 2(0.26134\ eV) + 2\left(\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \end{aligned} \tag{13.968}$$

From Eqs. (13.966-13.968), the total energy of the NO MO is:

$$E_{T+osc}(NO) = -34.43653\ eV + \bar{E}_{osc}(NO) = -34.43653\ eV + (-0.28658) = -34.72312\ eV \tag{13.969}$$

where the experimental ω_e was used for the $\hbar\sqrt{\dfrac{k}{\mu}}$ term.

The NO bond dissociation energy, $E_D(NO)$, is given by the difference between the sum of the energies of the N and O atoms and $E_{T+osc}(NO)$:

$$E_D(NO) = E(N) + E(O) - E_{T+osc}(NO) \tag{13.970}$$

where the energy of a nitrogen atom is [6]:

$$E(N) = -14.53414\ eV \tag{13.971}$$

and the energy of an oxygen atom is [6]:

$$E(O) = -13.61806\ eV \tag{13.972}$$

Thus, the NO bond dissociation energy, $E_D(NO)$, given by Eqs. (13.969-13.972) is:

$$\begin{aligned} E_D(NO) &= -(14.53414\ eV + 13.61806\ eV) - E_{T+osc}(NO) \\ &= -28.15220\ eV - (-34.72312\ eV) \\ &= 6.57092\ eV \end{aligned} \tag{13.973}$$

The experimental NO bond dissociation energy is [49]:

$$E_{D298}(NO) = 6.5353\ eV \tag{13.974}$$

The results of the determination of bond parameters of NO are given in Table 13.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

Table 13.1. The calculated and experimental bond parameters of H_3^+, D_3^+, OH, OD, H_2O, D_2O, NH, ND, NH_2, ND_2, NH_3, ND_3, CH, CD, CH_2, CH_3, CH_4, N_2, O_2, F_2, Cl_2, CN, CO, and NO.

Parameter	Calculated	Experimental	Ref. for Exp.
H_3^+ Bond Energy	4.373 eV	4.373 eV	8

Chapter 14

MORE POLYATOMIC MOLECULES AND HYDROCARBONS

Additional polyatomic molecules can be solved using similar principles as those used to solve hydrogen molecular ions and molecules wherein the hydrogen molecular orbitals (MOs) and hydrogen atomic orbitals serve as basis functions for the MOs. The MO must (1) be a solution of Laplace's equation to give a equipotential energy surface, (2) correspond to an orbital solution of the Newtonian equation of motion in an inverse-radius-squared central field having a constant total energy, (3) be stable to radiation, and (4) conserve the electron angular momentum of $\hbar$. Energy of the MO must be matched to that of the outermost atomic orbital of a bonding heteroatom in the case where a minimum energy is achieved with a direct bond to the AO. Alternatively, the MO is continuous with the AO containing paired electrons that do not particpate in the bond. Rather, they only provide a means for the energy matched MO to form a continuous equipotential energy surface. In the case that an independent MO is formed, the AO force balance causes the remaining electrons to be at lower energy and a smaller radius. In another case, the atomic orbital may hybridize in order to achieve a bond at an energy minimum, and the sharing of electrons between two or more such orbitals to form a MO permits the participating hybridized orbitals to decrease in energy through a decrease in the radius of one or more of the participating orbitals. Representative cases were solved. Specifically, the results of the determination of bond parameters of carbon dioxide (CO_2), nitrogen dioxide (NO_2), ethane (CH_3CH_3), ethylene (CH_2CH_2), acetylene ($CHCH$), benzene (C_6H_6), propane (C_3H_8), butane (C_4H_{10}), pentane (C_5H_{12}), hexane (C_6H_{14}), heptane (C_7H_{16}), octane (C_8H_{18}), nonane (C_9H_{20}), decane ($C_{10}H_{22}$), undecane ($C_{11}H_{24}$), dodecane ($C_{12}H_{26}$), and octadecane ($C_{18}H_{38}$) are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

CARBON DIOXIDE MOLECULE

The carbon dioxide molecule can be formed by the reaction of carbon monoxide and an oxygen atom:

$$CO + O \rightarrow CO_2 \tag{14.1}$$

Each equivalent bond in the carbon dioxide molecule comprises a double bond that is energy-matched to the filled $C2s$ orbital. Each such bond comprises 75% of a H_2-type MO with four paired electrons as a basis set such that three electrons can be assigned to each $C=O$ bond. Thus, the two $C2p$ electrons combine with the four $O2p$ electrons, two from each O, as a linear combination to form the two $C=O$ bonds of CO_2. The force balance equation and radius r_8 of the $2p$ shell of O is derived in the Eight-Electron Atoms section. With the formation of the H_2-type MOs by the contribution of two $2p$ electrons from each of the two O atoms, a factor of two increase of the central field on the remaining $O2p$ electrons arises. The resulting increased Coulombic as well as magnetic central forces decrease the radii of the $O2p$ shells such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of CO_2 is $C1s^2O_1 1s^2O_2 1s^2C2s^2O_1 2s^2O_2 2s^2O_1 2p^2O_2 2p^2\sigma^6_{O_2,C,O_1}$ where the subscripts designate the O atom, 1 or 2, σ designates the H_2-type MO, and the orbital arrangement is:

σ state

$\uparrow\downarrow \quad \uparrow\downarrow \quad \uparrow\downarrow$

2p state

$\uparrow\downarrow$ 0 $\qquad$ $\uparrow\downarrow$ 0

2s state

$\uparrow\downarrow \qquad \uparrow\downarrow \qquad \uparrow\downarrow$

1s state

$\uparrow\downarrow$ O $\qquad$ $\uparrow\downarrow$ C $\qquad$ $\uparrow\downarrow$ O (14.2)

Carbon dioxide is predicted to be diamagnetic in agreement with observations [1].

FORCE BALANCE OF THE $2p$ SHELL OF THE OXYGEN ATOM OF THE CARBON DIOXIDE MOLECULE

For each O atom, force balance for the outermost $2p$ electron of CO_2 (electron 6) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 6 and the other $2p$ electrons as well as the $2s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Eight-Electron Atoms section. The central Coulomb force on the outer-most $2p$ shell electron of CO (electron 6) due to the nucleus and the inner five electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele} = \frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2}\mathbf{i}_\mathbf{r} \tag{14.3}$$

for $r > r_5$. The $2p$ shell possess a +2 external electric field given by Eq. (10.92) for $r > r_6$. The energy is minimized with conservation of angular momentum. This condition is met when the diamagnetic force, $\mathbf{F}_{diamagnetic}$, of Eq. (10.82) due to the p-orbital contribution is given by:

$$\mathbf{F}_{diamagnetic} = -\left(\frac{2}{3}\right)\frac{\hbar^2}{4m_e r_6^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} = -\frac{2\hbar^2}{12m_e r_6^2 r_3}\sqrt{\frac{3}{4}}\mathbf{i}_\mathbf{r} \tag{14.4}$$

where $s = 1/2$. And, $\mathbf{F}_{mag\ 2}$ corresponding to the conserved spin and orbital angular momentum given by Eq. (10.157) is:

$$\mathbf{F}_{mag\ 2} = \frac{1}{Z}\frac{2\hbar^2}{m_e r_6^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{14.5}$$

The electric field external to the $2p$ shell given by Eq. (10.92) for $r > r_6$ gives rise to a second diamagnetic force, $\mathbf{F}_{diamagnetic\ 2}$, given by Eq. (10.93). $\mathbf{F}_{diamagnetic\ 2}$ due to the binding of the p-orbital electron having an electric field of +2 outside of its radius is:

$$\mathbf{F}_{diamagnetic\ 2} = -\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{m_e r_6^4}10\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{14.6}$$

The radius of the $2p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (14.3)) and diamagnetic (Eqs. (14.4) and (14.6)), and paramagnetic (Eq. (14.5)) forces as follows:

$$\frac{m_e v_6^2}{r_6} = \frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2} - \frac{2\hbar^2}{12m_e r_6^2 r_3}\sqrt{s(s+1)} + \frac{2\hbar^2}{Zm_e r_6^2 r_3}\sqrt{s(s+1)} - \left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_6^4 m_e}10\sqrt{s(s+1)} \tag{14.7}$$

Substitution of $v_6 = \frac{\hbar}{m_e r_6}$ (Eq. (1.35)) and $s = \frac{1}{2}$ into Eq. (14.7) gives:

$$\frac{\hbar^2}{m_e r_6^3} = \frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2} - \frac{2\hbar^2}{12m_e r_6^2 r_3}\sqrt{\frac{3}{4}} + \frac{2\hbar^2}{Zm_e r_6^2 r_3}\sqrt{\frac{3}{4}} - \left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_6^4 m_e}10\sqrt{\frac{3}{4}} \tag{14.8}$$

The quadratic equation corresponding to Eq. (14.8) is:

$$r_6^2-\frac{\dfrac{\hbar^2}{m_e}}{\left(\dfrac{(Z-5)e^2}{4\pi\varepsilon_0}-\left(\dfrac{2}{12}-\dfrac{2}{Z}\right)\dfrac{\hbar^2}{m_e r_3}\sqrt{\dfrac{3}{4}}\right)}r_6-\frac{\dfrac{\hbar^2}{m_e}\left[\dfrac{Z-6}{Z-5}\right]\left(1-\dfrac{\sqrt{2}}{2}\right)r_3 10\sqrt{\dfrac{3}{4}}}{\left(\dfrac{(Z-5)e^2}{4\pi\varepsilon_0}-\left(\dfrac{2}{12}-\dfrac{2}{Z}\right)\dfrac{\hbar^2}{m_e r_3}\sqrt{\dfrac{3}{4}}\right)}=0 \tag{14.9}$$

The solution of Eq. (14.9) using the quadratic formula is:

$$r_6=\frac{\dfrac{a_0}{\left((Z-5)-\left(\dfrac{2}{12}-\dfrac{2}{Z}\right)\dfrac{\sqrt{3}}{2r_3}\right)}\pm a_0\sqrt{\left(\dfrac{1}{\left((Z-5)-\left(\dfrac{2}{12}-\dfrac{2}{Z}\right)\dfrac{\sqrt{3}}{2r_3}\right)}\right)^2+\dfrac{20\sqrt{3}\left(\left[\dfrac{Z-6}{Z-5}\right]\left(1-\dfrac{\sqrt{2}}{2}\right)r_3\right)}{\left((Z-5)-\left(\dfrac{2}{12}-\dfrac{2}{Z}\right)\dfrac{\sqrt{3}}{2r_3}\right)}}}{2},\ r_3\ \textit{in units of}\ a_0 \tag{14.10}$$

The positive root of Eq. (14.10) must be taken in order that $r_6>0$. Substitution of $\frac{r_3}{a_0}=0.59020$ (Eq. (10.62) with $Z=8$) into Eq. (14.10) gives:

$$r_6=0.74776a_0 \tag{14.11}$$

ENERGIES OF THE $2s$ AND $2p$ SHELLS OF THE CARBON ATOM AND THE $2p$ SHELL OF THE OXYGEN ATOMS OF THE CARBON DIOXIDE MOLECULE

Consider the determination of the total energy of CO_2 from the reaction of a carbon atom with two oxygen atoms. With the formation of the H_2-type MO by the contribution of two $2p$ electrons from the C atom, the remaining outer-shell atomic electrons comprise the $2s$ electrons which are unchanged by bonding with two oxygen atoms. However, the total energy of the CO_2 molecule, which is subtracted from the sum of the energies of the oxygen atom and carbon monoxide molecule to determine the $O-CO$ bond energy, is increased by the ionization energies of C, C^+, O, and $2O^+$ given by Eqs. (14.12-14.15), respectively. Experimentally, the energies are [2]:

$$E(\textit{ionization};\ C)=11.26030\ eV \tag{14.12}$$

$$E(\textit{ionization};\ C^+)=24.38332\ eV \tag{14.13}$$

$$E(\textit{ionization};\ O)=13.61806\ eV \tag{14.14}$$

$$E(\textit{ionization};\ O^+)=35.11730\ eV \tag{14.15}$$

In addition, the central forces on the $2p$ shell of the O atom are increased with the formation of the σ MO which reduces the shell's radius and increases its total energy. The Coulombic energy terms of the total energy of each O atom at the new radius are calculated and added to the ionization energies of C, C^+, O, and $2O^+$, and the energy of the σ MO to give the total energy of CO_2. Then, the bond energy is determined from the total CO_2 energy.

The radius r_8 of each oxygen atom before bonding is given by Eq. (10.162):

$$r_8=a_0 \tag{14.16}$$

Using the initial radius r_8 of each O atom and the final radius r_6 of the $O2p$ shell (Eq. (14.11)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_T(O,2p)$ of the Coulombic energy change of the $O2p$ electrons of each O atom is determined using Eq. (10.102):

$$E_T(O,2p)=-\sum_{n=4}^{5}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_6}-\frac{1}{r_8}\right)=-(13.60580\ eV)(0.33733)(3+4)=-32.12759\ eV \tag{14.17}$$

FORCE BALANCE OF THE σ MO OF THE CARBON DIOXIDE MOLECULE

As in the case of H_2, the σ MO is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into the C atom for distances shorter than the radius of the $C2s$ shell; nor, can it extend into the O atom for distances shorter than the radius of the $O2p$ shell. Thus, the MO surface of each $C=O$ bond comprises a prolate spheroid that bridges and is continuous with the $2s$ and $2p$ shells of the O and C atoms whose nuclei serve as the foci. The energy of each prolate spheroid is matched to that of the $C2s$ and $O2p$ shells. As in the case of previous examples of energy-matched MOs such as OH and NH, the $C=O$-bond MO must comprise 75% of a H_2-type ellipsoidal MO in order to match potential, kinetic, and orbital

energy relationships. However, the paired electrons of the $C2s$ and $O2p$ shells are not involved in bonding. Rather, the AOs permit a continuous surface comprising the two $C=O$-bond MOs having six paired electrons, two from each of the C and the two O atoms:

$$2\left(0.75\ H_2\ MO\right)\rightarrow CO_2\ MO \tag{14.18}$$

The force balance of the CO_2 MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.18) and the energy matching condition between the carbon and oxygen components of the MO.

Similar to the OH and H_2O cases given by Eqs. (13.57) and (13.162), the H_2-type ellipsoidal MO comprises 75% of the CO_2 MO; so, the electron charge density in Eq. (11.65) is given by $-0.75e$. Thus, k' of each H_2-type-ellipsoidal-MO component of the CO_2 MO is given by Eq. (13.59). The distance from the origin of each $C=O$-bond MO to each focus c' is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C=O$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). Then, the solution of the semimajor axis a allows for the solution of the other axes of the prolate spheroidal and eccentricity of the CO_2 MO.

The energy components of V_e, V_p, T, V_m, and E_T of the CO_2 σ MO are the same as those of OH given by Eqs. (13.67-13.73), except that the terms based on charge are multiplied by four and the kinetic energy term is multiplied by two due to each σ-MO double bond:

$$E_T\left(C=O,\sigma\right)=-\frac{4e^2}{8\pi\varepsilon_0 c'}\left[\left(\frac{3}{2}\right)\ln\frac{a+c'}{a-c'}-1\right] \tag{14.19}$$

where $E_T\left(C=O,\sigma\right)$ is the total energy of each $C=O$ σ MO of CO_2. The total energy of a H_2-type ellipsoidal MO is given by Eqs. (11.212) and (13.75). A minimum energy is obtained when each double bond of the σ MO of CO_2 comprises the energy equivalent of four H_2-type ellipsoidal MOs. For each $C=O$ bond to match the energy of the $C2s$ orbital, the ionization energy of C and C^+ (Eqs. (14.12-14.13)) must be added for each bond of the double bond. Thus, the total energy of each $C=O$-bond MOs is:

$$\begin{aligned}E_T\left(C=O,\sigma\right)&=2\left(\begin{array}{l}2\left(-\frac{e^2}{8\pi\varepsilon_0 a_0}\left[\left(2\sqrt{2}-\sqrt{2}+\frac{\sqrt{2}}{2}\right)\ln\frac{\sqrt{2}+1}{\sqrt{2}-1}-\sqrt{2}\right]\right)\\ +E(ionization;\ C)+E(ionization;\ C^+)\end{array}\right)\\&=2\left(2\left(-31.63536831\ eV\right)+11.26030\ eV+24.38332\ eV\right)\\&=-55.25423\ eV\end{aligned} \tag{14.20}$$

$E_T\left(C=O,\sigma\right)$ given by Eq. (14.19) is set equal to Eq. (14.20):

$$\frac{4e^2}{8\pi\varepsilon_0 c'}\left[\left(\frac{3}{2}\right)\ln\frac{a+c'}{a-c'}-1\right]=e55.25423\ eV \tag{14.21}$$

From the energy relationship given by Eq. (14.21) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the CO_2 MO can be solved.

Substitution of Eq. (13.60) into Eq. (14.21) gives:

$$E_T\left(C=O,\sigma\right)=\frac{4e^2}{8\pi\varepsilon_0\sqrt{\frac{2aa_0}{3}}}\left[\left(\frac{3}{2}\right)\ln\frac{a+\sqrt{\frac{2aa_0}{3}}}{a-\sqrt{\frac{2aa_0}{3}}}-1\right]=e55.25423\ eV \tag{14.22}$$

The most convenient way to solve Eq. (14.22) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is

$$a=1.80703a_0=9.56239\ X\ 10^{-11}\ m \tag{14.23}$$

Substitution of Eq. (14.23) into Eq. (13.60) is:

$$c'=1.09758a_0=5.80815\ X\ 10^{-11}\ m \tag{14.24}$$

The internuclear distance given by multiplying Eq. (14.24) by two is:

$$2c'=2.19516a_0=1.16163\ X\ 10^{-10}\ m \tag{14.25}$$

The experimental bond distance is [3]

$$2c'=1.1600\ X\ 10^{-10}\ m \tag{14.26}$$

Substitution of Eqs. (14.23-14.24) into Eq. (13.62) is:

$$b=c=1.43550a_0=7.59636\ X\ 10^{-11}\ m \tag{14.27}$$

Substitution of Eqs. (14.23-14.24) into Eq. (13.63) is:

$$e=0.60740 \tag{14.28}$$

The C and O nuclei comprise the foci of each H_2-type ellipsoidal MO defined as $O=C=O$. Consider the left-hand $C=O$ bond of the two equivalent bonds in the absence of the right-hand bond. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $C2s$ AO are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where $r_n = r_4 = 0.84317a_0$ is the radius of the $C2s$ shell. Substitution of Eqs. (14.23-14.24) into Eq. (13.261) gives

$$\theta' = 54.53° \tag{14.29}$$

Then, the angle θ_{C2sAO} the radial vector of the $C2s$ AO makes with the internuclear axis is:

$$\theta_{C2sAO} = 180° - 54.53° = 125.47° \tag{14.30}$$

as shown in Figure 14.1. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{H_2MO}$ satisfies the following relationship:

$$r_4 \sin\theta_{C2sAO} = 0.84317a_0 \sin\theta_{C2sAO} = b\sin\theta_{H_2MO} \tag{14.31}$$

such that

$$\theta_{H_2MO} = \sin^{-1}\frac{0.84317a_0 \sin\theta_{C2sAO}}{b} = \sin^{-1}\frac{0.84317a_0 \sin 125.47°}{b} \tag{14.32}$$

with the use of Eq. (14.30). Substitution of Eq. (14.27) into Eq. (14.32) gives:

$$\theta_{H_2MO} = 28.58° \tag{14.33}$$

Then, the distance d_{H_2MO} along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by

$$d_{H_2MO} = a\cos\theta_{H_2MO} \tag{14.34}$$

Substitution of Eqs. (14.23) and (14.33) into Eq. (14.34) gives:

$$d_{H_2MO} = 1.58687a_0 = 8.39737\ X\ 10^{-11}\ m \tag{14.35}$$

The distance d_{C2sAO} along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals is given by

$$d_{C2sAO} = d_{H_2MO} - c' \tag{14.36}$$

Substitution of Eqs. (14.24) and (14.35) into Eq. (14.36) gives:

$$d_{C2sAO} = 0.48929a_0 = 2.58922\ X\ 10^{-11}\ m \tag{14.37}$$

The C and O nuclei comprise the foci of each H_2-type ellipsoidal MO defined as $O=C=O$. Consider the right-hand $C=O$ bond of the two equivalent bonds. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $O2p$ AO are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where $r_n = r_6 = 0.74776a_0$ is the radius of the $O2p$ shell. Substitution of Eqs. (14.23-14.24) into Eq. (13.261) gives

$$\theta' = 30.18° \tag{14.38}$$

Then, the angle θ_{O2pAO} the radial vector of the $O2p$ AO makes with the internuclear axis is:

$$\theta_{O2pAO} = 180° - 30.18° = 149.82° \tag{14.39}$$

as shown in Figure 14.1. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{H_2MO}$ satisfies the following relationship:

$$r_6 \sin\theta_{O2pAO} = 0.74776a_0 \sin\theta_{O2pAO} = b\sin\theta_{H_2MO} \tag{14.40}$$

such that

$$\theta_{H_2MO} = \sin^{-1}\frac{0.74776a_0 \sin\theta_{O2pAO}}{b} = \sin^{-1}\frac{0.74776a_0 \sin 149.82°}{b} \tag{14.41}$$

with the use of Eq. (14.39). Substitution of Eq. (14.27) into Eq. (14.41) gives:

$$\theta_{H_2MO} = 15.18° \tag{14.42}$$

Then, the distance d_{H_2MO} along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$d_{H_2MO} = a\cos\theta_{H_2MO} \tag{14.43}$$

Substitution of Eqs. (14.23) and (14.42) into Eq. (14.43) gives:

$$d_{H_2MO} = 1.74396a_0 = 9.22862\ X\ 10^{-11}\ m \tag{14.44}$$

The distance d_{O2pAO} along the internuclear axis from the origin of each O atom to the point of intersection of the orbitals is given by:

$$d_{2pAO} = d_{H_2MO} - c' \tag{14.45}$$

Substitution of Eqs. (14.24) and (14.44) into Eq. (14.45) gives:

$$d_{O2pAO} = 0.64637a_0 = 3.42047\ X\ 10^{-11}\ m \tag{14.46}$$

As shown in Eq. (14.18), each $C=O$ bond comprises a factor of 0.75 of the charge-density of double that of the H_2-type ellipsoidal MO. Using the electron configuration of CO_2 (Eq. (14.2)), the radii of the $C1s = 0.17113a_0$ (Eq. (10.51)), $C2s = 0.84317a_0$ (Eq. (10.62)), $O1s = 0.12739a_0$ (Eq. (10.51)), $O2s = 0.59020a_0$ (Eq. (10.62)), and $O2p = 0.74776a_0$ (Eq. (14.11)) shells and the parameters of the σ MO of CO_2 given by Eqs. (13.3-13.4), (14.23-14.25), and (14.27-14.28), the dimensional diagram and charge-density of the CO_2 MO are shown in Figures 14.1 and 14.2, respectively.

Figure 14.1. The cross section of the CO_2 MO showing the axes, σ MO (two H_2-type ellipsoidal MOs) with six paired electrons, with the C $1s$ and $2s$ AOs and the O $1s$, $2s$, and $2p$ AOs. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, r_4: radius of the $C2s$ shell having two paired electrons, r_6: radius of the $O2p$ shell having two paired electrons.

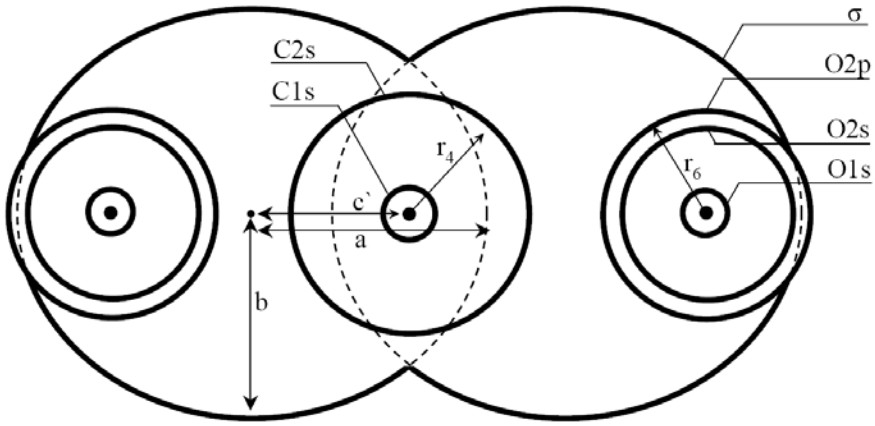

Figure 14.2. CO_2 MO comprising the σ MO (two H_2-type MOs) with C and two O atoms at the foci that have each donated two electrons to the σ MO. Consequently, the outer electrons of the carbon atom comprise the $C2s$ shell, and each $O2p$ shell has a smaller radius and a higher binding energy. (A) Color scale, translucent view of the charge-density of the CO_2 MO. (B) Off-center cut-away view showing each complete inner most $O1s$ shell, and moving radially, the $O2s$ shell, the $O2p$ shell, and the σ prolate spheroidal MO that has the corresponding O atom as a focus. Moving radially from the carbon-atom focus, the complete inner most $C1s$ shell, the $C2s$ shell, and the σ prolate spheroidal MOs are shown.

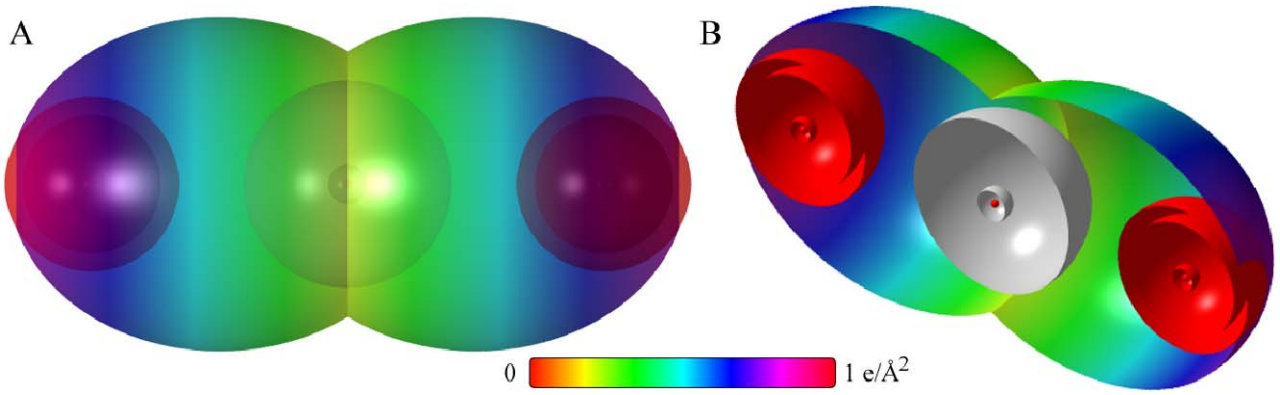

SUM OF THE ENERGIES OF THE σ MO AND THE AOS OF THE CARBON DIOXIDE MOLECULE

The energies of the CO_2 σ MO are given by the substitution of the semiprincipal axes (Eqs. (14.23-14.24) and (14.27)) into the energy equations of OH (Eqs. (13.67-13.73)), except that the terms based on charge are multiplied by four and the kinetic energy term is multiplied by two due to each σ-MO double bond:

$$V_e = 2^2\left(\frac{3}{4}\right)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -104.83940\ eV \tag{14.47}$$

$$V_p = 2^2\frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 49.58464\ eV \tag{14.48}$$

$$T = 2\left(\frac{3}{4}\right)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 14.50438\ eV \tag{14.49}$$

$$V_m = 2^2\left(\frac{3}{4}\right)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -14.50438\ eV \tag{14.50}$$

$$E_T = V_e + T + V_m + V_p \tag{14.51}$$

Substitution of Eqs. (13.60) and (14.47-14.50) into Eq. (14.51) gives:

$$E_T\left(C=O,\sigma\right) = V_e + T + V_m + V_p = \frac{-4e^2}{8\pi\varepsilon_0\sqrt{\frac{2aa_0}{3}}}\left[\left(\frac{3}{2}\right)\ln\frac{a+\sqrt{\frac{2aa_0}{3}}}{a-\sqrt{\frac{2aa_0}{3}}}-1\right] = -55.25476\ eV \tag{14.52}$$

where $E_T\left(C=O,\sigma\right)$ is the total energy of each $C=O$ σ MO of CO_2 given by Eq. (14.19) which is reiteratively matched to Eq. (14.20) within five-significant-figure round off error.

The total energy of CO_2, $E_T\left(CO_2\right)$, is given by the sum of $E(ionization;\ C)$ and $E(ionization;\ C^+)$, the sum of the energies of the first and second electrons of carbon (Eqs. (14.12-14.13)) donated to each double bond, the sum of $E(ionization;\ O)$ and two times $E(ionization;\ O^+)$, the energies of the first and second electrons of oxygen (Eqs. (14.14-14.15)) donated to the double bonds, two times $E_T\left(O,2p\right)$, the $O2p$ AO contribution due to the decrease in radius with the formation of each bond (Eq. (14.17)), and two times $E_T\left(C=O,\sigma\right)$, the σ MO contribution given by Eq. (14.22):

$$\begin{aligned}E_T\left(CO_2\right) &= \begin{pmatrix}E(ionization;\ C)+E(ionization;\ C^+)+E(ionization;\ O)\\ +2E(ionization;\ O^+)+2E_T\left(O,2p\right)+2E_T\left(C=O,\sigma\right)\end{pmatrix}\\ &= \begin{pmatrix}11.26030\ eV+24.38332\ eV+13.61806\ eV\\ +2\left(35.11730\ eV\right)+2\left(-32.12759\ eV\right)\\ -2\left(\frac{4e^2}{8\pi\varepsilon_0\sqrt{\frac{2aa_0}{3}}}\left(\left(\frac{3}{2}\right)\ln\frac{a+\sqrt{\frac{2aa_0}{3}}}{a-\sqrt{\frac{2aa_0}{3}}}-1\right)\right)\end{pmatrix}\\ &= \begin{pmatrix}11.26030\ eV+24.38332\ eV+13.61806\ eV\\ +2\left(35.11730\ eV\right)+2\left(-32.12759\ eV\right)-2\left(55.25423\ eV\right)\end{pmatrix} = -55.26841\ eV\end{aligned} \tag{14.53}$$

VIBRATION OF CO_2

The vibrational energy levels of CO_2 may be solved by determining the Morse potential curve from the energy relationships for the transition from a C atom and two O atoms whose parameters are given by Eqs. (10.115-10.123) and (10.154-10.163), respectively, to a C atom whose parameter r_4 is given by Eq. (10.61), two O atoms whose parameter r_6 is given by Eq. (14.11), and the σ CO_2 MO whose parameters are given by Eqs. (14.23-14.25) and (14.27-14.28). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K&P) [4] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

THE DOPPLER ENERGY TERMS OF THE CARBON DIOXIDE MOLECULE

The equations of the radiation reaction force of carbon dioxide are the same as those of OH with the substitution of the CO_2 parameters except that there is a factor of four increase in the central force in Eq. (13.140) due to the double bond. Using Eqs. (13.140-13.142), the angular frequency of the reentrant oscillation in the transition state is

$$\omega = \sqrt{\frac{\frac{4(0.75)e^2}{4\pi\varepsilon_0 b^3}}{m_e}} = 4.16331\ X\ 10^{16}\ rad/s \tag{14.54}$$

where b is given by Eq. (14.27). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K = \hbar\omega = \hbar 4.16331\ X\ 10^{16}\ rad/s = 27.40365\ eV \tag{14.55}$$

In Eq. (11.181), substitution of $E_T(CO_2)/2$ for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.55) for $\bar{E}_K$ gives the Doppler energy of the electrons of the reentrant orbit:

$$\bar{E}_D \cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}} = -27.63421\ eV\sqrt{\frac{2e(27.40365\ eV)}{m_e c^2}} = -0.28619\ eV \tag{14.56}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The transition state comprises $O--CO$, oxygen binding to CO. Vibration of the linear XYZ-molecular transition state corresponds to υ_3 [5] with the maximum kinetic energy localized to the nascent $C-O$ bond. In this case, the kinetic energy of the nuclei is the maximum for this bond. Thus, $\bar{E}_{Kvib}$ is the vibrational energy. The decrease in the energy of the CO_2 MO due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (14.56) and $\bar{E}_{Kvib}$, the vibrational energy. Using the experimental CO_2 $E_{vib}(\upsilon_3)$ of 2349 cm^{-1} $(0.29124\ eV)$ [6] for $\bar{E}_{Kvib}$ of the transition state, $\bar{E}_{osc}(CO_2)$ is:

$$\bar{E}_{osc}(CO_2) = \bar{E}_D + \bar{E}_{Kvib} = \bar{E}_D + E_{vib} \tag{14.57}$$

$$\bar{E}_{osc}(CO_2) = -0.28619\ eV + 0.29124\ eV = 0.00505\ eV \tag{14.58}$$

TOTAL AND BOND ENERGIES OF THE CARBON DIOXIDE MOLECULE

$E_{T+osc}(CO_2)$, the total energy of CO_2 including the Doppler term, is given by the sum of $E_T(CO_2)$ (Eq. (14.53)) and $\bar{E}_{osc}(CO_2)$ given by Eq. (14.58).

$$\begin{aligned}
E_{T+osc}(CO_2) &= \begin{pmatrix} 2(V_e + T + V_m + V_p) + E(ionization;\ C) \\ +E(ionization;\ C^+) + E(ionization;\ O) + 2E(ionization;\ O^+) \\ +2E_T(O,2p) + \bar{E}_{osc}(CO_2) \end{pmatrix} \\
&= \begin{pmatrix} 2E_T(C=O,\sigma) + E(ionization;\ C) + E(ionization;\ C^+) \\ +E(ionization;\ O) + 2E(ionization;\ O^+) \\ +2E_T(O,2p) + \bar{E}_{osc}(CO_2) \end{pmatrix} \\
&= E_T(CO_2) + \bar{E}_{osc}(CO_2)
\end{aligned} \tag{14.59}$$

$$\begin{aligned}
E_{T+osc}(CO_2) = \Bigg\{ & \begin{pmatrix} 2\left(\frac{-4e^2}{8\pi\varepsilon_0\sqrt{\frac{2aa_0}{3}}}\left(\left(\frac{3}{2}\right)\ln\frac{a+\sqrt{\frac{2aa_0}{3}}}{a-\sqrt{\frac{2aa_0}{3}}} - 1\right)\right) + E(ionization;\ C) \\ +E(ionization;\ C^+) + E(ionization;\ O) \\ +2E(ionization;\ O^+) - 2\sum_{O,n=4}^{5}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_6} - \frac{1}{r_8}\right) \end{pmatrix} \\
& \begin{pmatrix} 1 + \frac{1}{2}\sqrt{\frac{2\hbar\sqrt{\frac{\frac{4(0.75)e^2}{4\pi\varepsilon_0 b^3}}{m_e}}}{m_e c^2}} \end{pmatrix} + E_{vib} \Bigg\} \\
= & -55.26841\ eV - 0.28619\ eV + E_{vib}
\end{aligned} \tag{14.60}$$

From Eqs. (14.57-14.60), the total energy of the CO_2 MO is:

$$E_{T+osc}\left(CO_2\right) = -55.25476\ eV + \bar{E}_{osc}\left(CO_2\right) = -55.25476\ eV + 0.00505\ eV = -55.26336\ eV \tag{14.61}$$

where the experimental E_{vib} was used.

As in the case of the dissociation of the bond of the hydroxyl radical, an oxygen atom is formed with dissociation of CO_2. O has two unpaired electrons as shown in Eq. (13.55) which interact to stabilize the atom as shown by Eq. (10.161-10.162). The lowering of the energy of the reactants decreases the bond energy. Thus, the total energy of oxygen is reduced by the energy in the field of the two magnetic dipoles given by Eq. (7.46) and Eq. (13.101).

$$E(magnetic) = \frac{2\pi\mu_0 e^2\hbar^2}{m_e^2 a_0^3} = \frac{8\pi\mu_0\mu_B^2}{a_0^3} = 0.11441\ eV \tag{14.62}$$

The CO_2 bond dissociation energy, $E_D\left(CO_2\right)$, is given by the sum of the energies of the CO and the O atom minus the sum of $E_{T+osc}\left(CO_2\right)$ and $E(magnetic)$:

$$E_D\left(CO_2\right) = E\left(CO\right) + E\left(O\right) - \left(E(magnetic) + E_{T+osc}\left(CO_2\right)\right) \tag{14.63}$$

The energy of an oxygen atom is given by Eq. (14.14) and $E_T(CO)$ is given by the sum of the experimental energies of C (Eq. (14.12)), O (Eq. (14.14)), and the negative of the bond energy of CO (Eq. (13.914)):

$$E(CO) = -11.26030\ eV - 13.618060\ eV - 11.15696\ eV = -36.03532\ eV \tag{14.64}$$

The energy of O is given by the negative of the corresponding ionization energy given in Eq. (4.14). Thus, the CO_2 bond dissociation energy, $E_D\left(CO_2\right)$, given by the Eqs. (4.14) and (14.61-14.64) is:

$$\begin{aligned} E_D\left(CO_2\right) &= -\left(36.03532\ eV + 13.618060\ eV\right) - \left(E(magnetic) + E_{T+osc}\left(CO_2\right)\right) \\ &= -49.65338\ eV - \left(0.11441\ eV - 55.26336\ eV\right) \\ &= 5.49557\ eV \end{aligned} \tag{14.65}$$

The experimental CO_2 bond dissociation energy is [7]:

$$E_{D298}\left(CO_2\right) = 5.516\ eV \tag{14.66}$$

The results of the determination of bond parameters of CO_2 are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

NITROGEN DIOXIDE MOLECULE

The nitrogen dioxide molecule can be formed by the reaction of nitric oxide and an oxygen atom:

$$NO + O \rightarrow NO_2 \tag{14.67}$$

The bonding in the nitrogen dioxide molecule comprises two double bonds, each a H_2-type MO with four paired electrons wherein the central N atom is shared by both bonds such that six electrons can be assigned to the two $N=O$ bonds. Thus, two $N2p$ electrons combine with the four $O2p$ electrons, two from each O, as a linear combination to form the two overlapping $N=O$ bonds of NO_2. The force balance equation and radius r_7 of the $2p$ shell of N is derived in the Seven-Electron Atoms section. The force balance equation and radius r_8 of the $2p$ shell of O is derived in the Eight-Electron Atoms section. With the formation of each of the two H_2-type MOs by the contribution of two $2p$ electrons each from the N and O atoms, a diamagnetic force arises between the remaining outer shell atomic electrons, the $2s$ and $2p$ electrons of N and O, and the H_2-type MO. This force from N and O causes the H_2-type MO to move to greater principal axes than would result with the Coulombic force alone. But, the factor of two increase of the central field and the resulting increased Coulombic as well as magnetic central forces on the remaining N and O electrons decrease the radii of the corresponding shells such that the energy minimum is achieved that is lower than that of the reactant atoms. The resulting electron configuration of NO_2 is $N1s^2O_1 1s^2O_2 1s^2 N2s^2O_1 2s^2O_2 2s^2 N2p^1O_1 2p^2O_2 2p^2\sigma^6_{O_2,N,O_1}$ where the subscripts designate the O atom, 1 or 2, σ designates the H_2-type MO, and the orbital arrangement is:

σ state

$\underline{\uparrow\downarrow}\ \underline{\uparrow\downarrow}\ \underline{\uparrow\downarrow}$

2p state

$\underline{\uparrow\downarrow}$ $\underline{\uparrow}$ $\underline{\uparrow\downarrow}$

0 0 0

2s state

$\underline{\uparrow\downarrow}$ $\underline{\uparrow\downarrow}$ $\underline{\uparrow\downarrow}$ (14.68)

1s state

$\underline{\uparrow\downarrow}$ $\underline{\uparrow\downarrow}$ $\underline{\uparrow\downarrow}$

O N O

Nitrogen dioxide is predicted to be weakly paramagnetic in agreement with observations [1].

FORCE BALANCE OF THE $2p$ SHELL OF THE NITROGEN ATOM OF NITROGEN DIOXIDE

For the N atom, force balance for the outermost $2p$ electron of NO_2 (electron 5) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 5 and the $2s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Seven-Electron Atoms section. The central Coulomb force on the outer-most $2p$ shell electron of NO (electron 5) due to the nucleus and the inner four electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele} = \frac{(Z-4)e^2}{4\pi\varepsilon_0 r_5^2}\mathbf{i}_\mathbf{r} \tag{14.69}$$

for $r > r_4$. The $2p$ shell possess a +2 external electric field given by Eq. (10.92) for $r > r_5$. The energy is minimized with conservation of angular momentum. This condition is met when the magnetic forces of N in NO_2 are the same as those of N in NO. They are also the same as those of N in the nitrogen molecule with r_5 replacing r_6 and with an increase of the central field by an integer. The diamagnetic force, $\mathbf{F}_{diamagnetic}$, of Eq. (10.82) due to the p-orbital contribution is given by Eq. (13.918).

$$\mathbf{F}_{diamagnetic} = -\left(\frac{1}{3}\right)\frac{\hbar^2}{4m_e r_5^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} = -\frac{\hbar^2}{12m_e r_5^2 r_3}\sqrt{\frac{3}{4}}\mathbf{i}_\mathbf{r} \tag{14.70}$$

And, $\mathbf{F}_{mag\ 2}$ corresponding to the conserved orbital angular momentum of the three orbitals is also the same as that of NO_2 given by Eq. (13.919):

$$\mathbf{F}_{mag\ 2} = \frac{1}{Z}\frac{3\hbar^2}{m_e r_5^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{14.71}$$

The electric field external to the $2p$ shell given by Eq. (10.92) for $r > r_5$ gives rise to a second diamagnetic force, $\mathbf{F}_{diamagnetic\ 2}$, given by Eq. (10.93). $\mathbf{F}_{diamagnetic\ 2}$ due to the binding of the p-orbital electron having an electric field of +2 outside of its radius is given by Eq. (13.920):

$$\mathbf{F}_{diamagnetic\ 2} = -\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{m_e r_5^4}10\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{14.72}$$

The radius of the $2p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (14.69)) and diamagnetic (Eqs. (14.70) and (14.72)), and paramagnetic (Eq. (14.71)) forces as follows:

$$\frac{m_e v_5^2}{r_5} = \left(\begin{array}{l}\dfrac{(Z-4)e^2}{4\pi\varepsilon_0 r_5^2} - \dfrac{\hbar^2}{12m_e r_5^2 r_3}\sqrt{s(s+1)} + \dfrac{3\hbar^2}{Zm_e r_5^2 r_3}\sqrt{s(s+1)} \\ -\left[\dfrac{Z-5}{Z-4}\right]\left(1-\dfrac{\sqrt{2}}{2}\right)\dfrac{r_3\hbar^2}{r_5^4 m_e}10\sqrt{s(s+1)}\end{array}\right) \tag{14.73}$$

Substitution of $v_5 = \dfrac{\hbar}{m_e r_5}$ (Eq. (1.35)) and $s = \dfrac{1}{2}$ into Eq. (14.73) gives:

$$\frac{\hbar^2}{m_e r_5^3}=\frac{(Z-4)e^2}{4\pi\varepsilon_0 r_5^2}-\frac{\hbar^2}{12m_e r_5^2 r_3}\sqrt{\frac{3}{4}}+\frac{3\hbar^2}{Zm_e r_5^2 r_3}\sqrt{\frac{3}{4}}-\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_5^4 m_e}10\sqrt{\frac{3}{4}} \tag{14.74}$$

The quadratic equation corresponding to Eq. (14.74) is:

$$r_5^2-\frac{\frac{\hbar^2}{m_e}}{\left(\frac{(Z-4)e^2}{4\pi\varepsilon_0}-\left(\frac{1}{12}-\frac{3}{Z}\right)\frac{\hbar^2}{m_e r_3}\sqrt{\frac{3}{4}}\right)}r_5-\frac{\frac{\hbar^2}{m_e}\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3 10\sqrt{\frac{3}{4}}}{\left(\frac{(Z-4)e^2}{4\pi\varepsilon_0}-\left(\frac{1}{12}-\frac{3}{Z}\right)\frac{\hbar^2}{m_e r_3}\sqrt{\frac{3}{4}}\right)}=0 \tag{14.75}$$

The solution of Eq. (14.75) using the quadratic formula is:

$$r_5=\frac{\frac{a_0}{\left((Z-4)-\left(\frac{1}{12}-\frac{3}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}\pm a_0\sqrt{\left(\frac{1}{\left((Z-4)-\left(\frac{1}{12}-\frac{3}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}\right)^2+\frac{20\sqrt{3}\left(\left[\frac{Z-5}{Z-4}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3\right)}{\left((Z-4)-\left(\frac{1}{12}-\frac{3}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}}}{2},\ r_3 \text{ in units of } a_0 \tag{14.76}$$

The positive root of Eq. (14.76) must be taken in order that $r_5>0$. Substitution of $\frac{r_3}{a_0}=0.69385$ (Eq. (10.62) with $Z=7$) into Eq. (14.76) gives:

$$r_5=0.74841a_0 \tag{14.77}$$

FORCE BALANCE OF THE $2p$ SHELL OF EACH OXYGEN ATOM OF NITROGEN DIOXIDE

For each O atom, force balance for the outermost $2p$ electron of NO_2 (electron 6) is achieved between the centrifugal force and the Coulombic and magnetic forces that arise due to interactions between electron 6 and the other $2p$ electron as well as the $2s$-shell electrons due to spin and orbital angular momentum. The forces used are derived in the Eight-Electron Atoms section. The central Coulomb force on the outer-most $2p$ shell electron of NO_2 (electron 6) due to the nucleus and the inner five electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele}=\frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2}\mathbf{i}_\mathbf{r} \tag{14.78}$$

for $r>r_5$. The $2p$ shell possess an external electric field of +2 given by Eq. (10.92) for $r>r_6$. The energy is minimized with conservation of angular momentum. This condition is met when the magnetic forces of O in NO_2 are the same as those of O in NO. The diamagnetic force, $\mathbf{F}_{diamagnetic}$, of Eq. (10.82) due to the p-orbital contribution given by Eq. (13.927) is:

$$\mathbf{F}_{diamagnetic}=-\left(\frac{2}{3}\right)\frac{\hbar^2}{4m_e r_6^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r}=-\frac{2\hbar^2}{12m_e r_6^2 r_3}\sqrt{\frac{3}{4}}\mathbf{i}_\mathbf{r} \tag{14.79}$$

And, $\mathbf{F}_{mag\ 2}$ corresponding to the conserved spin and orbital angular momentum given by Eq. (13.928) is:

$$\mathbf{F}_{mag\ 2}=\frac{1}{Z}\frac{2\hbar^2}{m_e r_6^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{14.80}$$

The electric field external to the $2p$ shell given by Eq. (10.92) for $r>r_6$ gives rise to a second diamagnetic force, $\mathbf{F}_{diamagnetic\ 2}$, given by Eq. (10.93). $\mathbf{F}_{diamagnetic\ 2}$ due to the binding of the p-orbital electron having an electric field of +2 outside of its radius given by Eq. (13.929) is:

$$\mathbf{F}_{diamagnetic\ 2}=-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{m_e r_6^4}10\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{14.81}$$

In addition, the contribution of two $2p$ electrons in the formation of the σ MO gives rise to a paramagnetic force on the remaining paired $2p$ electrons. The force $\mathbf{F}_{mag\ 3}$ is given by Eq. (13.930) is:

$$\mathbf{F}_{mag\ 3}=\frac{\hbar^2}{4m_e r_6^3}\sqrt{s(s+1)}\mathbf{i}_{\mathbf{r}} \tag{14.82}$$

The radius of the $2p$ shell is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (14.78)) and diamagnetic (Eqs. (14.79) and (14.81)), and paramagnetic (Eqs. (14.80) and (14.82)) forces as follows:

$$\frac{m_e v_6^2}{r_6}=\begin{pmatrix}\frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2}-\frac{2\hbar^2}{12m_e r_6^2 r_3}\sqrt{s(s+1)}+\frac{2\hbar^2}{Zm_e r_6^2 r_3}\sqrt{s(s+1)}\\ -\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_6^4 m_e}10\sqrt{s(s+1)}+\frac{\hbar^2}{4m_e r_6^3}\sqrt{s(s+1)}\end{pmatrix} \tag{14.83}$$

Substitution of $v_6=\frac{\hbar}{m_e r_6}$ (Eq. (1.35)) and $s=\frac{1}{2}$ into Eq. (14.83) gives:

$$\frac{\hbar^2}{m_e r_6^3}-\frac{\hbar^2}{4m_e r_6^3}\sqrt{\frac{3}{4}}=\frac{(Z-5)e^2}{4\pi\varepsilon_0 r_6^2}-\frac{2\hbar^2}{12m_e r_6^2 r_3}\sqrt{\frac{3}{4}}+\frac{2\hbar^2}{Zm_e r_6^2 r_3}\sqrt{\frac{3}{4}}-\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)\frac{r_3\hbar^2}{r_6^4 m_e}10\sqrt{\frac{3}{4}} \tag{14.84}$$

The quadratic equation corresponding to Eq. (14.84) is:

$$r_6^2-\frac{\frac{\hbar^2}{m_e}\left(1-\frac{\sqrt{3}}{8}\right)}{\left(\frac{(Z-5)e^2}{4\pi\varepsilon_0}-\left(\frac{2}{12}-\frac{2}{Z}\right)\frac{\hbar^2}{m_e r_3}\sqrt{\frac{3}{4}}\right)}r_6-\frac{\frac{\hbar^2}{m_e}\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3 10\sqrt{\frac{3}{4}}}{\left(\frac{(Z-5)e^2}{4\pi\varepsilon_0}-\left(\frac{2}{12}-\frac{2}{Z}\right)\frac{\hbar^2}{m_e r_3}\sqrt{\frac{3}{4}}\right)}=0 \tag{14.85}$$

The solution of Eq. (14.85) using the quadratic formula is:

$$r_6=\frac{\frac{a_0\left(1-\frac{\sqrt{3}}{8}\right)}{\left((Z-5)-\left(\frac{2}{12}-\frac{2}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}\pm a_0\sqrt{\left(\frac{1-\frac{\sqrt{3}}{8}}{\left((Z-5)-\left(\frac{2}{12}-\frac{2}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}\right)^2+\frac{20\sqrt{3}\left(\left[\frac{Z-6}{Z-5}\right]\left(1-\frac{\sqrt{2}}{2}\right)r_3\right)}{\left((Z-5)-\left(\frac{2}{12}-\frac{2}{Z}\right)\frac{\sqrt{3}}{2r_3}\right)}}}{2},\ r_3\ \textit{in units of}\ a_0 \tag{14.86}$$

The positive root of Eq. (14.86) must be taken in order that $r_6>0$. Substitution of $\frac{r_3}{a_0}=0.59020$ (Eq. (10.62) with $Z=8$) into Eq. (14.86) gives:

$$r_6=0.70460a_0 \tag{14.87}$$

ENERGIES OF THE $2p$ SHELLS OF THE NITROGEN ATOM AND OXYGEN ATOMS OF NITROGEN DIOXIDE

Consider the determination of the total energy of NO_2 from the reaction of a nitrogen atom with two oxygen atoms. With the formation of each H_2-type MO by the contribution of two $2p$ electrons from each of the N and the two O atoms, the total energy of the NO_2 molecule, which is subtracted from the sum of the energies of the nitrogen and oxygen atoms to determine the bond energy, is increased by the ionization energies of N, N^+, O, and $2O^+$ given by Eqs. (14.88-14.91), respectively. Experimentally, the energies are [2]:

$$E(\textit{ionization};\ N)=14.53414\ eV \tag{14.88}$$

$$E(\textit{ionization};\ N^+)=29.6013\ eV \tag{14.89}$$

$$E(\textit{ionization};\ O)=13.61806\ eV \tag{14.90}$$

$$E(\textit{ionization};\ O^+)=35.11730\ eV \tag{14.91}$$

In addition, the central forces on the $2p$ shells of the N and O atoms are increased with the formation of the σ MOs which reduces each shell's radius and increases its total energy. The change per bond is the same as that of NO since the final radii given by Eq. (14.77) and (14.87) are the same for NO and NO_2. The Coulombic energy terms of the total energy of the N and O atoms at the new radii are calculated and added to the ionization energies of N, N^+, O, and $2O^+$, and the energy of the

σ MOs to give the total energy of NO_2. Then, the bond energy is determined from the total NO_2 energy.

The radius r_7 of the nitrogen atom before bonding is given by Eq. (10.142).

$$r_7 = 0.93084a_0 \tag{14.92}$$

Using the initial radius r_7 of the N atom and the final radius r_5 of the $N2p$ shell (Eq. (14.77)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_T(N,2p)$ of the Coulombic energy change of the $N2p$ electrons of the N atom is determined using Eq. (10.102):

$$E_T(N,2p) = -\sum_{n=4}^{4}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_5}-\frac{1}{r_7}\right) = -(13.60580\ eV)(0.26186)(3) = -10.68853\ eV \tag{14.93}$$

The radius r_8 of the oxygen atom before bonding is given by Eq. (10.162).

$$r_8 = a_0 \tag{14.94}$$

Using the initial radius r_8 of the O atom and the final radius r_6 of the $O2p$ shell (Eq. (14.87)) and by considering that the central Coulombic field decreases by an integer for each successive electron of the shell, the sum $E_T(O,2p)$ of the Coulombic energy change of the $O2p$ electrons of the O atom is determined using Eq. (10.102).

$$E_T(O,2p) = \sum_{n=4}^{5}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_6}-\frac{1}{r_8}\right) = (13.60580\ eV)\left(0.41925a_0^{-1}\right)(3+4) = -39.92918\ eV \tag{14.95}$$

FORCE BALANCE OF THE σ MO OF NITROGEN DIOXIDE

The force balance can be considered due to a second pair of two electrons binding to a molecular ion having $+2e$ at each focus and a first bound pair. Then, the forces are the same as those of a molecule ion having $+e$ at each focus. The diamagnetic force $\mathbf{F}_{diamagneticMO1}$ for each σ-MO of the NO_2 molecule due to the two, paired electrons in the $O2p$ shell is given by Eq. (13.633) with $n_e = 2$:

$$\mathbf{F}_{diamagneticMO1} = \frac{\hbar^2}{2m_e a^2 b^2} D\mathbf{i}_\xi \tag{14.96}$$

This is also the corresponding force of NO given by Eq. (13.942). $\mathbf{F}_{diamagneticMO2}$ of the nitrogen dioxide molecule comprising nitrogen with charge $Z_1 = 7$ and $|L_1| = \hbar$ and $|L_2| = \sqrt{\frac{3}{4}}\hbar$ and the two oxygen atoms, each with $Z_2 = 8$ and $|L_3| = \hbar$ is given by the corresponding sum of the contributions. Using Eq. (13.835), $\mathbf{F}_{diamagneticMO2}$ for NO_2 is:

$$\mathbf{F}_{diamagneticMO2} = \left(\frac{1}{Z_1}+\frac{\sqrt{\frac{3}{4}}}{Z_1}+\frac{2}{Z_2}\right)\frac{\hbar^2}{2m_e a^2 b^2} D\mathbf{i}_\xi \tag{14.97}$$

This is also the corresponding force of NO given by Eq. (13.943) except the term due to oxygen is twice that of NO due to the two oxygen atoms of NO_2. The general force balance equation for the σ-MO of the nitrogen dioxide molecule given by Eqs. (11.200), and (14.97-14.98) is also the same as that of CN (Eq. (14.836)) except for the doubling of the $\frac{2}{Z_2}$ term due to the two oxygen atoms:

$$\frac{\hbar^2}{m_e a^2 b^2} D = \frac{e^2}{8\pi\varepsilon_0 ab^2} D + \frac{\hbar^2}{2m_e a^2 b^2} D - \left(1+\frac{1}{Z_1}+\frac{\sqrt{\frac{3}{4}}}{Z_1}+\frac{2}{Z_2}\right)\frac{\hbar^2}{2m_e a^2 b^2} D \tag{14.98}$$

$$\frac{\hbar^2}{m_e a^2 b^2} D = \frac{e^2}{8\pi\varepsilon_0 ab^2} D - \left(\frac{1}{Z_1}+\frac{\sqrt{\frac{3}{4}}}{Z_1}+\frac{2}{Z_2}\right)\frac{\hbar^2}{2m_e a^2 b^2} D \tag{14.99}$$

$$\left(2+\frac{1}{Z_1}+\frac{\sqrt{\frac{3}{4}}}{Z_1}+\frac{2}{Z_2}\right)\frac{\hbar^2}{2m_e a^2 b^2} D = \frac{e^2}{8\pi\varepsilon_0 ab^2} D \tag{14.100}$$

$$a = \left(2 + \frac{1}{Z_1} + \frac{\sqrt{\frac{3}{4}}}{Z_1} + \frac{2}{Z_2} \right) a_0 \tag{14.101}$$

Substitution of $Z_1 = 7$ and $Z_2 = 8$ into Eq. (14.101) gives:

$$a = 2.51658 a_0 = 1.33171\ X\ 10^{-10}\ m \tag{14.102}$$

Substitution of Eq. (14.102) into Eq. (11.79) is:

$$c' = 1.12173 a_0 = 5.93596\ X\ 10^{-11}\ m \tag{14.103}$$

The internuclear distance given by multiplying Eq. (14.103) by two is:

$$2c' = 2.24347 a_0 = 1.18719\ X\ 10^{-10}\ m \tag{14.104}$$

The experimental bond distance is [3]:

$$2c' = 1.193\ X\ 10^{-10}\ m \tag{14.105}$$

Substitution of Eqs. (14.102-14.103) into Eq. (11.80) is:

$$b = c = 2.25275 a_0 = 1.19210\ X\ 10^{-10}\ m \tag{14.106}$$

Substitution of Eqs. (14.102-14.103) into Eq. (11.67) is:

$$e = 0.44574 \tag{14.107}$$

The bonding in the nitrogen dioxide molecule comprises two double bonds, each a H_2-type MO with four paired electrons wherein the central N atom is shared by both bonds such that six electrons can be assigned to the two $N = O$ bonds. Thus, two $N2p$ electrons combine with the four $O2p$ electrons, two from each O, as a linear combination to form the two overlapping $N = O$ bonds of NO_2. Using the electron configuration of NO_2 (Eq. (14.68)), the radii of the $N1s = 0.14605 a_0$ (Eq. (10.51)), $N2s = 0.69385 a_0$ (Eq. (10.62)), $N2p = 0.74841 a_0$ (Eq. (14.77)), $O1s = 0.12739 a_0$ (Eq. (10.51)), $O2s = 0.59020 a_0$ (Eq. (10.62)), and $O2p = 0.70460 a_0$ (Eq. (14.87)) shells and the parameters of the σ MOs of NO_2 given by Eqs. (13.3-13.4), (14.102-14.104), and (14.106-14.107), the dimensional diagram and charge-density of the NO_2 MO are shown in Figures 14.3 and 14.4, respectively.

Figure 14.3. The cross section of the NO_2 MO showing the axes, σ MOs (two H_2-type ellipsoidal MOs) with six paired electrons, with the N $1s$, $2s$, and $2p$ AOs and the O $1s$, $2s$, and $2p$ AOs. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, r_5: radius of the $N2p$ shell having one unpaired electron, r_6: radius of each $O2p$ shell having two paired electrons.

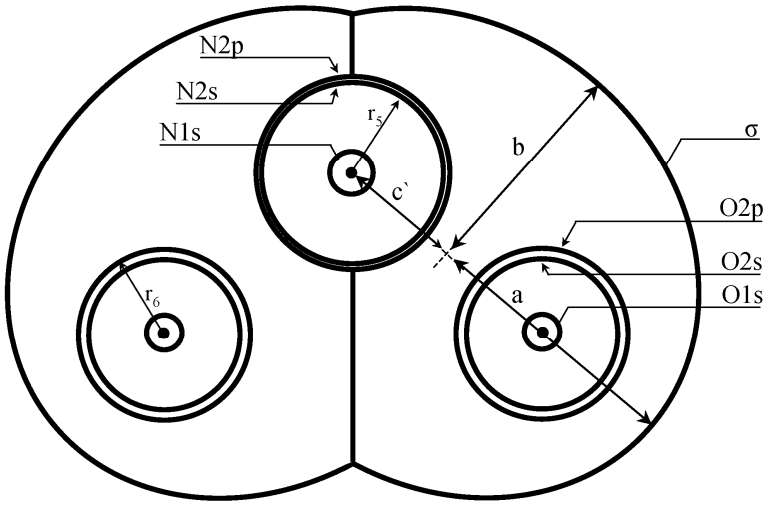

Figure 14.4. NO_2 MO comprising two σ MOs (H_2-type MOs) with N and O atoms at the foci that have each donated two electrons to the σ MOs and have smaller radii and higher binding energies as a consequence. (A)-(B) Top and side color scale, translucent views of the charge-density of the NO_2 MO. (C) Off-center cut-away view showing the complete inner most $N1s$ shell, and moving radially, the $N2s$ shell, the $N2p$ shell, and the σ prolate spheroidal MOs that each have the N atom as a focus. Moving radially from each oxygen-atom focus, the complete innermost $O1s$ shell, the $O2s$ shell, the $O2p$ shell, and the σ prolate spheroidal MOs are shown.

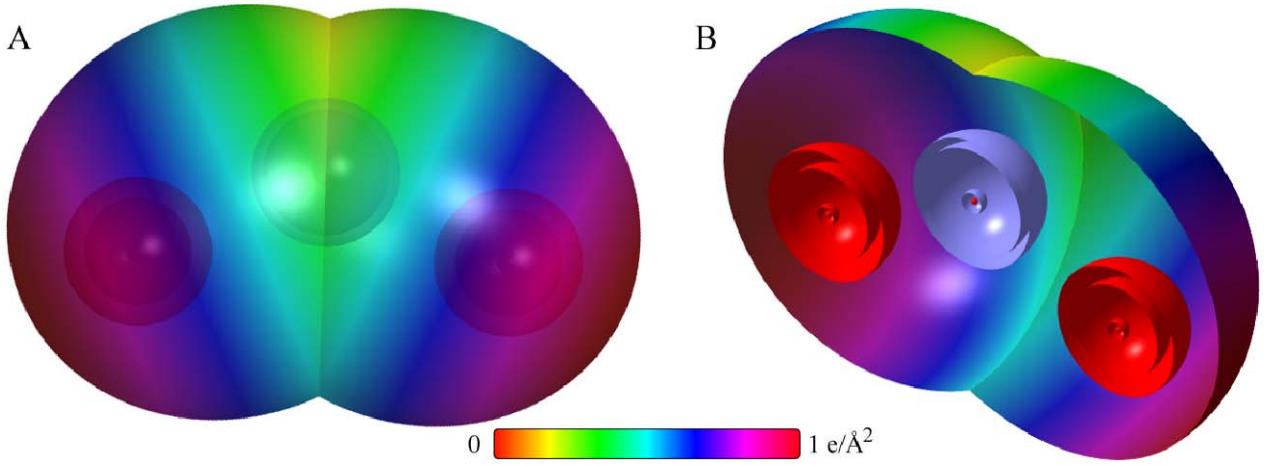


SUM OF THE ENERGIES OF THE σ MOS AND THE AOS OF NITROGEN DIOXIDE

The energies of each NO_2 σ MO are the same as those of NO (Eqs. (13.954-13.958)). They are given by the substitution of the semiprincipal axes (Eqs. (14.102-14.103) and (14.106)) into the energy equations (Eqs. (11.207-11.212)) of H_2 except that the terms based on charge are multiplied by four and the kinetic energy term is multiplied by two due to the σ-MO double bond with two pairs of paired electrons:

$$V_e = 2^2 \frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} \ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -93.03032\ eV \tag{14.108}$$

$$V_p = 2^2 \frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 48.51704\ eV \tag{14.109}$$

$$T = 2\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}} \ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 9.24176\ eV \tag{14.110}$$

$$V_m = 2^2 \frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}} \ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -9.24176\ eV \tag{14.111}$$

$$E_T = V_e + T + V_m + V_p \tag{14.112}$$

Substitution of Eqs. (11.79) and (14.108-14.111) into Eq. (14.112) gives:

$$E_T\left(N=O,\sigma\right) = \frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2}}}\left(8\ln\frac{a+\sqrt{\frac{aa_0}{2}}}{a-\sqrt{\frac{aa_0}{2}}} - 4\right) = -44.51329\ eV \tag{14.113}$$

where $E_T\left(N=O,\sigma\right)$ is the total energy of each σ MO of NO_2. The total energy of NO_2, $E_T\left(NO_2\right)$, is given by the sum of $E(ionization; N)$ and $E(ionization; N^+)$, the sum of the energies of the first and second electrons of nitrogen (Eqs. (14.88-14.89)) donated to each double bond, the sum of $E(ionization; O)$ and two times $E(ionization; O^+)$, the energies of the first and second electrons of oxygen (Eqs. (14.90-14.91)) donated to the double bonds, $E_T\left(N,2p\right)$, the $N2p$ AO contribution due to the decrease in radius with the formation of each bond (Eq. (14.93)), two times $E_T\left(O,2p\right)$, the $O2p$ AO contribution due to the decrease in radius with the formation of each bond (Eq. (14.95)), and two times $E_T\left(N=O,\sigma\right)$, the σ MO contribution given by Eq. (14.113):

$$E_T\left(NO_2\right)=\begin{pmatrix} E(ionization;\ N)+E(ionization;\ N^+) \\ +E(ionization;\ O)+2E(ionization;\ O^+)+E_T\left(N,2p\right) \\ +2E_T\left(O,2p\right)+2E_T\left(N=O,\sigma\right) \end{pmatrix}$$
$$=\begin{pmatrix} 14.53414\ eV+29.6013\ eV+13.61806\ eV \\ +2\left(35.11730\ eV\right)+\left(-10.68853\ eV\right)+2\left(-39.92918\ eV\right) \\ +2\left(\dfrac{-e^2}{8\pi\varepsilon_0\sqrt{\dfrac{aa_0}{2}}}\left(8\ln\dfrac{a+\sqrt{\dfrac{aa_0}{2}}}{a-\sqrt{\dfrac{aa_0}{2}}}-4\right)\right) \end{pmatrix}$$
$$=\begin{pmatrix} 14.53414\ eV+29.6013\ eV+13.61806\ eV \\ +2\left(35.11730\ eV\right)+\left(-10.68853\ eV\right) \\ +2\left(-39.92918\ eV\right)+2\left(-44.51329\ eV\right) \end{pmatrix}=-51.58536\ eV \tag{14.114}$$

VIBRATION OF NO_2

The vibrational energy levels of NO_2 may be solved by determining the Morse potential curve from the energy relationships for the transition from a N atom and two O atoms whose parameters are given by Eqs. (10.134-10.143) and (10.154-10.163), respectively, to a N atom whose parameter r_5 is given by Eq. (14.77), two O atoms whose parameter r_6 is given by Eq. (14.87), and the σ MOs whose parameters are given by Eqs. (14.102-14.104) and (14.106-14.107). As shown in the Vibration of Hydrogen-type Molecular Ions section, the harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K&P) [4] and after Eq. (11.134). Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods.

THE DOPPLER ENERGY TERMS OF NITROGEN DIOXIDE

The equations of the radiation reaction force of nitrogen dioxide are the same as those of NO with the substitution of the NO_2 parameters. Using Eq. (13.961), the angular frequency of the reentrant oscillation in the transition state is:

$$\omega=\sqrt{\frac{4e^2}{4\pi\varepsilon_0 a^3 m_e}}=2.07110\ X\ 10^{16}\ rad/s \tag{14.115}$$

where a is given by Eq. (14.102). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K=\hbar\omega=\hbar 2.07110\ X\ 10^{16}\ rad/s=13.63231\ eV \tag{14.116}$$

In Eq. (11.181), substitution of $E_T\left(NO_2\right)/2$ for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.116) for $\bar{E}_K$ gives the Doppler energy of the electrons of the reentrant orbit:

$$\bar{E}_D\cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}}=-25.79268\ eV\sqrt{\frac{2e\left(13.63231\ eV\right)}{m_e c^2}}=-0.18840\ eV \tag{14.117}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The transition state comprises $O--NO$, oxygen binding to NO. As in the case of CO_2 bond formation, vibration in the transition state corresponds to υ_3 [5] with the maximum kinetic energy localized to the nascent $N-O$ bond. In this case, the kinetic energy of the nuclei is the maximum for this bond. Thus, $\bar{E}_{Kvib}$ is the vibrational energy. The decrease in the energy of the NO_2 MO due to the reentrant orbit in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (14.117) and $\bar{E}_{Kvib}$, the vibrational energy. Using the experimental NO_2 $E_{vib}\left(\upsilon_3\right)$ of 1618 cm^{-1} $\left(0.20061\ eV\right)$ [6] for $\bar{E}_{Kvib}$ of the transition state, $\bar{E}_{osc}\left(NO_2\right)$ is:

$$\bar{E}_{osc}\left(NO_2\right)=\bar{E}_D+\bar{E}_{Kvib}=\bar{E}_D+E_{vib} \tag{14.118}$$

$$\bar{E}_{osc}\left(NO_2\right)=-0.18840\ eV+0.20061\ eV=0.01221\ eV \tag{14.119}$$

TOTAL AND BOND ENERGIES OF NITROGEN DIOXIDE

$E_{T+osc}(NO_2)$, the total energy of NO_2 including the Doppler term, is given by the sum of $E_T(NO_2)$ (Eq. (14.114)) and $\bar{E}_{osc}(NO_2)$ given by Eq. (14.119).

$$\begin{aligned} E_{T+osc}(NO_2) &= \begin{pmatrix} 2\left(V_e+T+V_m+V_p\right)+E(ionization;\ N)+E(ionization;\ N^+) \\ +E(ionization;\ O)+2E(ionization;\ O^+) \\ +E_T(N,2p)+2E_T(O,2p)+\bar{E}_{osc}(NO_2) \end{pmatrix} \\ &= \begin{pmatrix} 2E_T(N=O,\sigma)+E(ionization;\ N)+E(ionization;\ N^+) \\ +E(ionization;\ O)+2E(ionization;\ O^+) \\ +E_T(N,2p)+2E_T(O,2p)+\bar{E}_{osc}(NO_2) \end{pmatrix} \\ &= E_T(NO_2)+\bar{E}_{osc}(NO_2) \end{aligned} \tag{14.120}$$

$$\begin{aligned} E_{T+osc}(NO_2) = \Bigg\{ & \Bigg(2\left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2}}} \left(8\ln\frac{a+\sqrt{\frac{aa_0}{2}}}{a-\sqrt{\frac{aa_0}{2}}}-4 \right) \right) \\ & E(ionization;\ N)+E(ionization;\ N^+) \\ & +E(ionization;\ O)+2E(ionization;\ O^+) \\ & -\sum_{N,n=4}^{4}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_5}-\frac{1}{r_7}\right)-2\sum_{O,n=4}^{5}\frac{(Z-n)e^2}{8\pi\varepsilon_0}\left(\frac{1}{r_6}-\frac{1}{r_8}\right) \Bigg) \\ & \left(1+\frac{1}{2}\sqrt{\frac{2\hbar\sqrt{\frac{4e^2}{4\pi\varepsilon_0 a^3}}}{m_e c^2}} \right)+E_{vib} \Bigg\} \\ = & -51.58536\ eV-0.18840\ eV+E_{vib} \end{aligned} \tag{14.121}$$

From Eqs. (14.119-14.121), the total energy of the NO_2 MO is:

$$\begin{aligned} E_{T+osc}(NO_2) &= -51.58536\ eV+\bar{E}_{osc}(NO_2) \\ &= -51.58536\ eV+0.01221\ eV \\ &= -51.57315\ eV \end{aligned} \tag{14.122}$$

where the experimental E_{vib} was used.

As in the case of the dissociation of the bond of the hydroxyl radical, an oxygen atom is formed with dissociation of NO_2. O has two unpaired electrons as shown in Eq. (13.55) which interact to stabilize the atom as shown by Eq. (10.161-10.162). The lowering of the energy of the reactants decreases the bond energy. Thus, the total energy of oxygen is reduced by the energy in the field of the two magnetic dipoles given by Eq. (7.46) and Eq. (13.101).

$$E(magnetic)=\frac{2\pi\mu_0 e^2\hbar^2}{m_e^2 a_0^3}=\frac{8\pi\mu_0\mu_B^2}{a_0^3}=0.11441\ eV \tag{14.123}$$

The NO_2 bond dissociation energy, $E_D(NO_2)$, is given by the sum of the energies of the NO and the O atom minus the sum of $E_{T+osc}(NO_2)$ and $E(magnetic)$:

$$E_D(NO_2)=E(NO)+E(O)-\left(E(magnetic)+E_{T+osc}(NO_2)\right) \tag{14.124}$$

The energy of an oxygen atom is given by the negative of Eq. (14.90), and $E_T(NO)$ is given by the sum of the experimental energies of N (negative of Eq. (14.88)), O, and the negative of the bond energy of NO (Eq. (13.974)).

$$E(NO)=-14.53414\ eV-13.618060\ eV-6.53529\ eV=-34.68749\ eV \tag{14.125}$$

Thus, the NO_2 bond dissociation energy, $E_D(NO_2)$, given by Eqs. (4.90) and (14.112-14.125) is:

$$\begin{aligned} E_D(NO_2) &= -(34.68749\ eV + 13.618060\ eV) - (E(magnetic) + E_{T+osc}(NO_2)) \\ &= -48.30555\ eV - (0.11441\ eV - 51.57315\ eV) = 3.15319\ eV \end{aligned} \tag{14.126}$$

The experimental NO_2 bond dissociation energy is [7]:

$$E_{D298}(NO_2) = 3.161\ eV \tag{14.127}$$

BOND ANGLE OF NO_2

The NO_2 MO comprises a linear combination of two $N=O$-bond MOs. A bond is also possible between the two O atoms of the $N=O$ bonds. Such $O=O$ bonding would decrease the $N=O$ bond strength since electron density would be shifted from the $N=O$ bonds to the $O=O$ bond. Thus, the bond angle between the two $N=O$ bonds is determined by the condition that the total energy of the H_2-type ellipsoidal MO between the terminal O atoms of the $N=O$ bonds is zero. From Eqs. (11.79) and (13.228), the distance from the origin to each focus of the $O=O$ ellipsoidal MO is:

$$c' = a\sqrt{\frac{\hbar^2 4\pi\varepsilon_0}{m_e e^2 2a}} = \sqrt{\frac{aa_0}{2}} \tag{14.128}$$

The internuclear distance from Eq. (13.229) is:

$$2c' = 2\sqrt{\frac{aa_0}{2}} \tag{14.129}$$

The length of the semiminor axis of the prolate spheroidal $O=O$ MO $b=c$ is given by Eq. (13.167).

The component energies and the total energy E_T of the $O=O$ bond are given by the energy equations (Eqs. (11.207-11.212), (11.213-11.217), and (11.239)) of H_2 except that the terms based on charge are multiplied by four and the kinetic energy term is multiplied by two due to the $O=O$ double bond with two pairs of paired electrons. Substitution of Eq. (14.128) into Eqs. (11.207-11.212) gives:

$$0 = \left[\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2}}} \left(8\ln\frac{a+\sqrt{\frac{aa_0}{2}}}{a-\sqrt{\frac{aa_0}{2}}} - 4 \right) \left[1 + \sqrt{\frac{2\hbar\sqrt{\frac{4e^2}{4\pi\varepsilon_0 a^3}}}{m_e c^2}} \right] \right. \\ \left. + \frac{1}{2}\hbar\sqrt{\frac{\frac{4e^2}{8\pi\varepsilon_0 a^3} - \frac{4e^2}{8\pi\varepsilon_0 (a+c')^3}}{8m_p}} \right] \tag{14.130}$$

From the energy relationship given by Eq. (14.130) and the relationship between the axes given by Eqs. (14.128-14.129) and (13.167-14.168), the dimensions of the $O=O$ MO can be solved.

The most convenient way to solve Eq. (14.130) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a = 8.3360a_0 = 4.4112\ X\ 10^{-10}\ m \tag{14.131}$$

Substitution of Eq. (14.131) into Eq. (14.128) gives:

$$c' = 2.0416a_0 = 1.0804\ X\ 10^{-10}\ m \tag{14.132}$$

The internuclear distance given by multiplying Eq. (14.132) by two is:

$$2c' = 4.0831a_0 = 2.1607\ X\ 10^{-10}\ m \tag{14.133}$$

Substitution of Eqs. (14.131-14.132) into Eq. (14.167) gives:

$$b = c = 8.0821a_0 = 4.2769\ X\ 10^{-10}\ m \tag{14.134}$$

Substitution of Eqs. (14.131-14.132) into Eq. (14.168) gives:

$$e = 0.2449 \tag{14.135}$$

From, $2c'_{C=C}$ (Eq. (14.133)), the distance between the two O atoms when the total energy of the corresponding MO is zero (Eq. (14.130)), and $2c'_{N=O}$ (Eq. (14.104)), the internuclear distance of each $N=O$ bond, the corresponding bond angle can be determined from the law of cosines. Using, Eqs. (13.240-13.242), the bond angle θ between the $N=O$ bonds is:

$$\theta = \cos^{-1}\left(\frac{2\left(2.24347\right)^2 - \left(4.0831\right)^2}{2\left(2.24347\right)^2}\right) = \cos^{-1}\left(-0.6562\right) = 131.012° \tag{14.136}$$

The experimental angle between the $N = O$ bonds is [3]:

$$\theta = 134.1° \tag{14.137}$$

The results of the determination of bond parameters of NO_2 are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

ETHANE MOLECULE (CH_3CH_3)

The ethane molecule CH_3CH_3 is formed by the reaction of two methyl radicals:

$$CH_3 + CH_3 \rightarrow CH_3CH_3 \tag{14.138}$$

CH_3CH_3 can be solved using the same principles as those used to solve CH_3, wherein the $2s$ and $2p$ shells of each C hybridize to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. First, two sets of three H atomic orbitals (AOs) combine with two sets of three carbon $2sp^3$ HOs to form two methyl groups comprising a linear combination of six diatomic H_2-type MOs developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section. Then, the two CH_3 groups bond by forming a H_2-type MO between the remaining $C2sp^3$ HO on each carbon.

FORCE BALANCE OF THE $C-C$-BOND MO OF ETHANE

CH_3CH_3 comprises a chemical bond between two CH_3 radicals wherein each methyl radical comprises three chemical bonds between carbon and hydrogen atoms. The solution of the parameters of CH_3 is given in the Methyl Radical (CH_3) section. Each $C-H$ bond of CH_3 having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of 75% H_2-type ellipsoidal MO and 25% $C2sp^3$ HO. The proton of the H atom and the nucleus of the C atom are along each internuclear axis and serve as the foci. As in the case of H_2, each of the three $C-H$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $C2sp^3$ HO for distances shorter than the radius of the $C2sp^3$ shell since it is energetically unfavorable. Thus, each MO surface comprises a prolate spheroid at the H proton that is continuous with the $C2sp^3$ shell at the C atom whose nucleus serves as the other focus. The electron configuration and the energy, $E\left(C,2sp^3\right)$, of the $C2sp^3$ shell is given by Eqs. (13.422) and (13.428), respectively. The central paramagnetic force due to spin of each $C-H$ bond is provided by the spin-pairing force of the CH_3 MO that has the symmetry of an s orbital that superimposes with the $C2sp^3$ orbitals such that the corresponding angular momenta are unchanged.

Two CH_3 radicals bond to form CH_3CH_3 by forming a MO between the two remaining $C2sp^3$-HO electrons of the two carbon atoms. However, in this case, the sharing of electrons between two $C2sp^3$ HOs to form a molecular orbital (MO) comprising two spin-paired electrons permits each $C2sp^3$ HO to decrease in radius and energy.

As in the case of the $C-H$ bonds, the $C-C$-bond MO is a prolate-spheroidal-MO surface that cannot extend into $C2sp^3$ HO for distances shorter than the radius of the $C2sp^3$ shell of each atom. Thus, the MO surface comprises a partial prolate spheroid in between the carbon nuclei and is continuous with the $C2sp^3$ shell at each C atom. The energy of the H_2-type ellipsoidal MO is matched to that of the $C2sp^3$ shell. As in the case of previous examples of energy-matched MOs such as those of OH, NH, CH, and the $C=O$-bond MO of CO_2, the $C-C$-bond MO of ethane must comprise 75% of a H_2-type ellipsoidal MO in order to match potential, kinetic, and orbital energy relationships. Thus, the $C-C$-bond MO must comprise two $C2sp^3$ HOs and 75% of a H_2-type ellipsoidal MO divided between the two $C2sp^3$ HOs:

$$2\,C2sp^3 + 0.75\,H_2\ MO \rightarrow C-C-bond\ MO \tag{14.139}$$

The linear combination of the H_2-type ellipsoidal MO with each $C2sp^3$ HO further comprises an excess 25% charge-density contribution from each $C2sp^3$ HO to the $C-C$-bond MO to achieve an energy minimum. The force balance of the $C-C$-bond

MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.139) and the energy matching condition between the $C2sp^3$-HO components of the MO.

Similarly, the energies of each CH_3 MO involve each $C2sp^3$ and each $H1s$ electron with the formation of each $C-H$ bond. The sum of the energies of the H_2-type ellipsoidal MOs is matched to that of the $C2sp^3$ shell. This energy is determined by the considering the effect of the donation of 25% electron density from the two $C2sp^3$ HOs to the $C-C$-bond MO. The $2sp^3$ hybridized orbital arrangement given by Eq. (13.422) is:

$$\begin{array}{cccc} & 2\text{sp}^3 \text{ state} & & \\ \uparrow & \uparrow & \uparrow & \uparrow \\ \hline 0,0 & 1,\text{-}1 & 1,0 & 1,1 \end{array} \tag{14.140}$$

where the quantum numbers (ℓ, m_ℓ) are below each electron. The total energy of the state is given by the sum over the four electrons. The sum $E_T\left(C,2sp^3\right)$ of calculated energies of C, C^+, C^{2+}, and C^{3+} from Eqs. (10.123), (10.113-10.114), (10.68), and (10.48), respectively, is:

$$E_T\left(C,2sp^3\right)=64.3921\ eV+48.3125\ eV+24.2762\ eV+11.27671\ eV=148.25751\ eV \tag{14.141}$$

which agrees well with the sum of 148.02532 eV from the experimental [2] values. Consider the case of the $C2sp^3$ HO of each methyl radical. The orbital-angular-momentum interactions cancel such that the energy of the $E_T\left(C,2sp^3\right)$ is purely Coulombic. By considering that the central field decreases by an integer for each successive electron of the shell, the radius r_{2sp^3} of the $C2sp^3$ shell may be calculated from the Coulombic energy using Eq. (10.102):

$$r_{2sp^3}=\sum_{n=2}^{5}\frac{(Z-n)e^2}{8\pi\varepsilon_0\left(e148.25751\ eV\right)}=\frac{10e^2}{8\pi\varepsilon_0\left(e148.25751\ eV\right)}=0.91771a_0 \tag{14.142}$$

where $Z=6$ for carbon. Using Eqs. (10.102) and (14.142), the Coulombic energy $E_{Coulomb}\left(C,2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is:

$$E_{Coulomb}\left(C,2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{2sp^3}}=\frac{-e^2}{8\pi\varepsilon_0 0.91771a_0}=-14.82575\ eV \tag{14.143}$$

During hybridization, the spin-paired $2s$ electrons are promoted to the $C2sp^3$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (13.152) at the initial radius of the $2s$ electrons. From Eq. (10.62) with $Z=6$, the radius r_3 of the $C2s$ shell is:

$$r_3=0.84317a_0 \tag{14.144}$$

Using Eqs. (13.152) and (14.144), the unpairing energy is:

$$E(magnetic)=\frac{2\pi\mu_0 e^2\hbar^2}{m_e^2\left(r_3\right)^3}=\frac{8\pi\mu_0\mu_B^2}{\left(0.84317a_0\right)^3}=0.19086\ eV \tag{14.145}$$

Using Eqs. (14.143) and (14.145), the energy $E\left(C,2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is:

$$E\left(C,2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{2sp^3}}+\frac{2\pi\mu_0 e^2\hbar^2}{m_e^2\left(r_3\right)^3}=-14.82575\ eV+0.19086\ eV=-14.63489\ eV \tag{14.146}$$

Next, consider the formation of the $C-C$-bond MO of ethane from two methyl radicals, each having a $C2sp^3$ electron with an energy given by Eq. (14.146). The total energy of the state is given by the sum over the four electrons. The sum $E_T\left(C_{ethane},2sp^3\right)$ of calculated energies of $C2sp^3$, C^+, C^{2+}, and C^{3+} from Eqs. (10.123), (10.113-10.114), (10.68), and (10.48), respectively, is:

$$\begin{aligned} E_T\left(C_{ethane},2sp^3\right)&=-\left(64.3921\ eV+48.3125\ eV+24.2762\ eV+E\left(C,2sp^3\right)\right)\\ &=-\left(64.3921\ eV+48.3125\ eV+24.2762\ eV+14.63489\ eV\right)\\ &=-151.61569\ eV \end{aligned} \tag{14.147}$$

where $E\left(C,2sp^3\right)$ is the sum of the energy of C, $-11.27671\ eV$, and the hybridization energy. The orbital-angular-momentum

interactions also cancel such that the energy of the $E_T\left(C_{ethane},2sp^3\right)$ is purely Coulombic.

The sharing of electrons between two $C2sp^3$ HOs to form a $C-C$-bond MO permits each participating hybridized orbital to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each $C2sp^3$ HO donates an excess of 25% of its electron density to the $C-C$-bond MO to form an energy minimum. By considering this electron redistribution in the ethane molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{ethane2sp^3}$ of the $C2sp^3$ shell of ethane may be calculated from the Coulombic energy using Eq. (10.102).

$$r_{ethane2sp^3}=\left(\sum_{n=2}^{5}(Z-n)-0.25\right)\frac{e^2}{8\pi\varepsilon_0\left(e151.61569\ eV\right)}=\frac{9.75e^2}{8\pi\varepsilon_0\left(e151.61569\ eV\right)}=0.87495a_0 \tag{14.148}$$

Using Eqs. (10.102) and (14.148), the Coulombic energy $E_{Coulomb}\left(C_{ethane},2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is:

$$E_{Coulomb}\left(C_{ethane},2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{ethane2sp^3}}=\frac{-e^2}{8\pi\varepsilon_0 0.87495a_0}=-15.55033\ eV \tag{14.149}$$

During hybridization, the spin-paired $2s$ electrons are promoted to the $C2sp^3$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (13.152). Using Eqs. (14.145) and (14.149), the energy $E\left(C_{ethane},2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is:

$$E\left(C_{ethane},2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{ethane2sp^3}}+\frac{2\pi\mu_0 e^2\hbar^2}{m_e^2\left(r_3\right)^3}=-15.55033\ eV+0.19086\ eV=-15.35946\ eV \tag{14.150}$$

Thus, $E_T\left(C-C,2sp^3\right)$, the energy change of each $C2sp^3$ shell with the formation of the $C-C$-bond MO is given by the difference between Eq. (14.146) and Eq. (14.150).

$$E_T\left(C-C,2sp^3\right)=E\left(C_{ethane},2sp^3\right)-E\left(C,2sp^3\right)=-15.35946\ eV-\left(-14.63489\ eV\right)=-0.72457\ eV \tag{14.151}$$

The H_2-type ellipsoidal MO comprises 75% of the $C-C$-bond MO shared between two $C2sp^3$ HOs corresponding to the electron charge density in Eq. (11.65) of $\frac{-0.75e}{2}$. But, the additional 25% charge-density contribution to the $C-C$-bond MO causes the electron charge density in Eq. (11.65) to be $\frac{-e}{2}=-0.5e$. Thus, the force constant k' to determine the ellipsoidal parameter c' in terms of the central force of the foci given by Eq. (11.65) is:

$$k'=\frac{(0.5)2e^2}{4\pi\varepsilon_0} \tag{14.152}$$

The distance from the origin to each focus c' is given by substitution of Eq. (14.152) into Eq. (13.60). Thus, the distance from the origin of the $C-C$-bond MO to each focus c' is given by:

$$c'=a\sqrt{\frac{\hbar^2 4\pi\varepsilon_0}{m_e e^2 a}}=\sqrt{aa_0} \tag{14.153}$$

The internuclear distance from Eq. (14.153) is:

$$2c'=2\sqrt{aa_0} \tag{14.154}$$

The length of the semiminor axis of the prolate spheroidal $C-C$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of the $C-C$-bond MO. Since the $C-C$-bond MO comprises a H_2-type-ellipsoidal MO that transitions to the $C_{ethane}2sp^3$ HO of each carbon, the energy $E\left(C_{ethane},2sp^3\right)$ in Eq. (14.150) adds to that of the H_2-type ellipsoidal MO to give the total energy of the $C-C$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the $C-C$-bond MO are solved. Similarly, $E\left(C_{ethane},2sp^3\right)$ is added to the energy of the H_2-type ellipsoidal MO of each $C-H$ bond of the methyl groups to give its total energy. From the energy equation and the relationship between the axes, the dimensions of the equivalent $C-H$-bond MOs of the methyl groups in ethane are solved.

The general equations for the energy components of V_e, V_p, T, V_m, and E_T of the $C-C$-bond MO are the same as those of the CH MO as well as each $C-H$-bond MO of the methyl groups except that energy of the $C_{ethane}2sp^3$ HO is used. Since the prolate spheroidal H_2-type MO transitions to the $C_{ethane}2sp^3$ HO of each carbon and the energy of the $C_{ethane}2sp^3$ shell must remain constant and equal to the $E\left(C_{ethane},2sp^3\right)$ given by Eq. (14.150), the total energy $E_T\left(C-C,\sigma\right)$ of the σ component of the $C-C$-bond MO is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $C_{ethane}2sp^3$ HO and the H_2-type ellipsoidal MO that forms the σ component of the $C-C$-bond MO as given by Eq. (14.139) with the electron charge redistribution. Using Eqs. (13.431) and (14.150), $E_T\left(C-C,\sigma\right)$ is given by:

$$E_T\left(C-C,\sigma\right)=E_T+E\left(C_{ethane},2sp^3\right)=-\frac{e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-15.35946\ eV \tag{14.155}$$

To match the boundary condition that the total energy of the entire the H_2-type ellipsoidal MO is given by Eqs. (11.212) and (13.75), $E_T\left(C-C,\sigma\right)$ given by Eq. (14.155) is set equal to Eq. (13.75):

$$E_T\left(C-C,\sigma\right)=-\frac{e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-15.35946\ eV=-31.63536831\ eV \tag{14.156}$$

From the energy relationship given by Eq. (14.156) and the relationship between the axes given by Eqs. (14.153-14.154) and (13.62-13.63), the dimensions of the $C-C$-bond MO can be solved.

Substitution of Eq. (14.153) into Eq. (14.156) gives:

$$\frac{e^2}{8\pi\varepsilon_0\sqrt{aa_0}}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{aa_0}}{a-\sqrt{aa_0}}-1\right]=e16.27589 \tag{14.157}$$

The most convenient way to solve Eq. (14.157) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is

$$a=2.10725a_0=1.11511\ X\ 10^{-10}\ m \tag{14.158}$$

Substitution of Eq. (14.158) into Eq. (14.153) gives:

$$c'=1.45164a_0=7.68173\ X\ 10^{-11}\ m \tag{14.159}$$

The internuclear distance given by multiplying Eq. (14.159) by two is:

$$2c'=2.90327a_0=1.53635\ X\ 10^{-10}\ m \tag{14.160}$$

The experimental bond distance is [3]:

$$2c'=1.5351\ X\ 10^{-10}\ m \tag{14.161}$$

Substitution of Eqs. (14.158-14.159) into Eq. (13.62) gives:

$$b=c=1.52750a_0=8.08317\ X\ 10^{-11}\ m \tag{14.162}$$

Substitution of Eqs. (14.158-14.159) into Eq. (13.63) gives:

$$e=0.68888 \tag{14.163}$$

The nucleus of the C atoms comprise the foci of the H_2-type ellipsoidal MO. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $C_{ethane}2sp^3$ HO are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where $r_n=r_{ethane2sp^3}=0.87495a_0$ is the radius of the $C_{ethane}2sp^3$ shell. Substitution of Eqs. (14.158-14.159) into Eq. (13.261) gives:

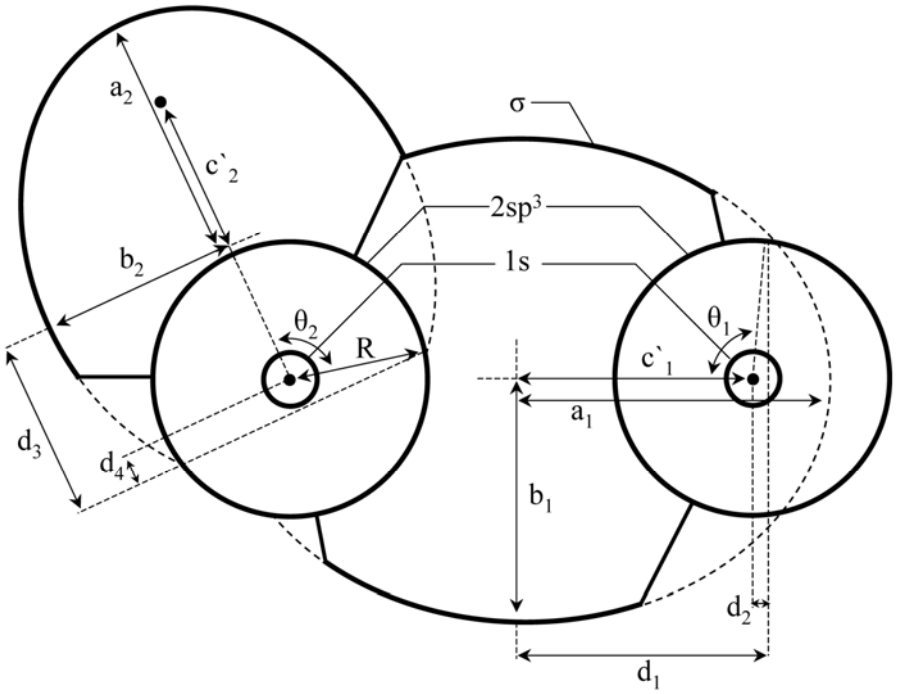
$$\theta'=67.33° \tag{14.164}$$

Then, the angle $\theta_{C-C_{ethane}2sp^3HO}$ the radial vector of the $C2sp^3$ HO makes with the internuclear axis is:

$$\theta_{C-C_{ethane}2sp^3HO}=180°-67.33°=112.67° \tag{14.165}$$

as shown in Figure 14.5.

Figure 14.5. The cross section of the $C-C$-bond MO (σ MO) and one $C-H$-bond MO of ethane showing the axes, angles, and point of intersection of each H_2-type ellipsoidal MO with the corresponding $C_{ethane}2sp^3$ HO. The continuation of each H_2-type-ellipsoidal-MO basis element of the $C-C$ bond and the $C-H$-bond beyond the intersection point with each $C_{ethane}2sp^3$ shell and σ MO is shown as dashed since each only serves to solve the energy match with the $C_{ethane}2sp^3$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of each intersection point. The actual charge density is shown by the solid lines. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, $d_1 : d_{C-C_{ethane},H_2MO}$, $\theta_1 : \theta_{C-C_{ethane}2sp^3HO}$, $d_2 : d_{C-C_{ethane}2sp^3HO}$, $R : r_{ethaneC2sp^3}$, $d_3 : d_{C-H_{ethane},H_2MO}$, $\theta_2 : \theta_{C-H_{ethane}2sp^3HO}$, and $d_4 : d_{C-H_{ethane}2sp^3HO}$.



Consider the right-hand intersection point. The Cartesian **i**-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian **j**-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{C-C_{ethane},H_2MO}$ satisfies the following relationship:

$$r_{ethane2sp^3} \sin\theta_{C-C_{ethane}2sp^3HO} = 0.87495a_0 \sin\theta_{C-C_{ethane}2sp^3HO} = b\sin\theta_{C-C_{ethane},H_2MO} \tag{14.166}$$

such that

$$\theta_{C-C_{ethane},H_2MO} = \sin^{-1}\frac{0.87495a_0 \sin\theta_{C-C_{ethane}2sp^3HO}}{b} = \sin^{-1}\frac{0.87495a_0 \sin 112.67°}{b} \tag{14.167}$$

with the use of Eq. (14.166). Substitution of Eq. (14.162) into Eq. (14.167) gives:

$$\theta_{C-C_{ethane},H_2MO} = 31.91° \tag{14.168}$$

Then, the distance d_{C-C_{ethane},H_2MO} along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$d_{C-C_{ethane},H_2MO} = a\cos\theta_{C-C_{ethane},H_2MO} \tag{14.169}$$

Substitution of Eqs. (14.158) and (14.168) into Eq. (14.169) gives:

$$d_{C-C_{ethane},H_2MO} = 1.78885a_0 = 9.46617\ X\ 10^{-11}\ m \tag{14.170}$$

The distance $d_{C-C_{ethane}2sp^3HO}$ along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals is given by:

$$d_{C-C_{ethane}2sp^3HO} = d_{C-C_{ethane},H_2MO} - c' \tag{14.171}$$

Substitution of Eqs. (14.159) and (14.170) into Eq. (14.171) gives:

$$d_{C-C_{ethane}2sp^3HO} = 0.33721a_0 = 1.78444\ X\ 10^{-11}\ m \tag{14.172}$$

FORCE BALANCE OF THE CH_3 MOS OF ETHANE

Each of the two equivalent CH_3 MOs must comprise three $C-H$ bonds with each comprising 75% of a H_2-type ellipsoidal MO and a $C2sp^3$ HO as given by Eq. (13.540):

$$3\left[1\ C2sp^3 + 0.75\ H_2\ MO\right] \rightarrow CH_3\ MO \tag{14.173}$$

The force balance of the CH_3 MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.540) and the energy matching condition between the hydrogen and $C2sp^3$ HO components of the MO.

The force constant k' to determine the ellipsoidal parameter c' of the each H_2-type-ellipsoidal-MO component of the CH_3 MO in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus c' is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $C-H$-bond MO. Since each of the three prolate spheroidal $C-H$-bond MOs comprises an H_2-type-ellipsoidal MO that transitions to the $C_{ethane}2sp^3$ HO of ethane, the energy $E\left(C_{ethane},2sp^3\right)$ of Eq. (14.150) adds to that of the three corresponding H_2-type ellipsoidal MOs to give the total energy of the CH_3 MO. From the energy equation and the relationship between the axes, the dimensions of the CH_3 MO are solved.

The energy components of V_e, V_p, T, and V_m are the same as those of methyl radical, three times those of CH corresponding to the three $C-H$ bonds except that energy of the $C_{ethane}2sp^3$ HO is used. Since each prolate spheroidal H_2-type MO transitions to the $C_{ethane}2sp^3$ HO and the energy of the $C_{ethane}2sp^3$ shell must remain constant and equal to the $E\left(C_{ethane},2sp^3\right)$ given by Eq. (14.150), the total energy $E_{T_{ethane}}\left(CH_3\right)$ of the CH_3 MO is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $C_{ethane}2sp^3$ HO and the three H_2-type ellipsoidal MOs that forms the CH_3 MO as given by Eq. (13.540). Using Eq. (13.431), $E_{T_{ethane}}\left(CH_3\right)$ is given by:

$$E_{T_{ethane}}\left(CH_3\right) = E_T + E\left(C_{ethane},2sp^3\right) = -\frac{3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-15.35946\ eV \tag{14.174}$$

$E_{T_{ethane}}\left(CH_3\right)$ given by Eq. (14.174) is set equal to three times the energy of the H_2-type ellipsoidal MO minus two times the Coulombic energy of H given by Eq. (13.542):

$$E_T\left(CH_3\right) = -\frac{3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-15.35946\ eV = -67.69450\ eV \tag{14.175}$$

From the energy relationship given by Eq. (14.175) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the CH_3 MO can be solved.

Substitution of Eq. (13.60) into Eq. (14.175) gives:

$$\frac{3e^2}{8\pi\varepsilon_0\sqrt{\frac{2aa_0}{3}}}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{2aa_0}{3}}}{a-\sqrt{\frac{2aa_0}{3}}}-1\right] = e52.33505 \tag{14.176}$$

The most convenient way to solve Eq. (14.176) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a = 1.64469a_0 = 8.70331\ X\ 10^{-11}\ m \tag{14.177}$$

Substitution of Eq. (14.177) into Eq. (14.60) gives:

$$c' = 1.04712a_0 = 5.54111\ X\ 10^{-11}\ m \tag{14.178}$$

The internuclear distance given by multiplying Eq. (14.178) by two is:

$$2c' = 2.09424a_0 = 1.10822\ X\ 10^{-10}\ m \tag{14.179}$$

The experimental bond distance is [3]:

$$2c' = 1.0940\ X\ 10^{-10}\ m \tag{14.180}$$

Substitution of Eqs. (14.177-14.178) into Eq. (14.62) gives:

$$b = c = 1.26828a_0 = 6.71145\ X\ 10^{-11}\ m \tag{14.181}$$

Substitution of Eqs. (14.177-14.178) into Eq. (13.63) gives:

$$e = 0.63667 \tag{14.182}$$

The nucleus of the H atom and the nucleus of the C atom comprise the foci of each H_2-type ellipsoidal MO. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $C_{ethane}2sp^3$ HO are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where $r_n = r_{ethane\,2sp^3} = 0.87495a_0$ is the radius of the $C_{ethane}2sp^3$ shell. Substitution of Eqs. (14.177-14.178) into Eq. (13.261) gives:

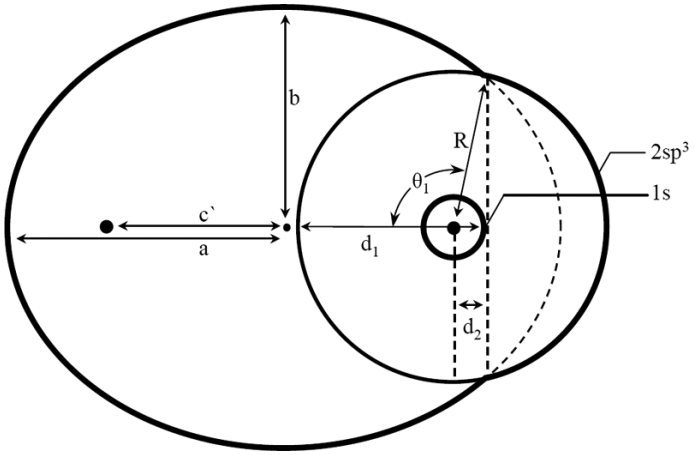
$$\theta' = 79.34° \tag{14.183}$$

Then, the angle $\theta_{C-H_{ethane}2sp^3HO}$ the radial vector of the $C2sp^3$ HO makes with the internuclear axis is:

$$\theta_{C-H_{ethane}2sp^3HO} = 180° - 79.34° = 100.66° \tag{14.184}$$

as shown in Figure 14.6.

Figure 14.6. The cross section of one $C-H$-bond MO of ethane showing the axes, angles, and point of intersection of the H_2-type ellipsoidal MO with the $C_{ethane}2sp^3$ HO. The continuation of the H_2-type-ellipsoidal-MO basis element beyond the intersection point with the $C_{ethane}2sp^3$ shell is shown as dashed since it only serves to solve the energy match with the $C_{ethane}2sp^3$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of the intersection point. The actual charge density is shown by the solid lines. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, $d_1 : d_{C-H_{ethane},H_2MO}$, $\theta_1 : \theta_{C-H_{ethane}2sp^3HO}$, $d_2 : d_{C-H_{ethane}2sp^3HO}$, and $R : r_{ethane2sp^3}$.



The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{C-H_{ethane},H_2MO}$ satisfies the following relationship:

$$r_{ethane2sp^3} \sin\theta_{C-H_{ethane}2sp^3HO} = 0.87495a_0 \sin\theta_{C-H_{ethane}2sp^3HO} = b\sin\theta_{C-H_{ethane},H_2MO} \tag{14.185}$$

such that

$$\theta_{C-H_{ethane},H_2MO} = \sin^{-1}\frac{0.87495a_0 \sin\theta_{C-H_{ethane}2sp^3HO}}{b} = \sin^{-1}\frac{0.87495a_0 \sin 100.66°}{b} \tag{14.186}$$

with the use of Eq. (14.184). Substitution of Eq. (14.181) into Eq. (14.186) gives:

$$\theta_{C-H_{ethane},H_2MO} = 42.68° \tag{14.187}$$

Then, the distance d_{C-H_{ethane},H_2MO} along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$d_{C-H_{ethane},H_2MO} = a\cos\theta_{C-H_{ethane},H_2MO} \tag{14.188}$$

Substitution of Eqs. (14.177) and (14.187) into Eq. (14.188) gives:

$$d_{C-H_{ethane},H_2MO} = 1.20901a_0 = 6.39780\ X\ 10^{-11}\ m \tag{14.189}$$

The distance $d_{C-H_{ethane}2sp^3HO}$ along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals is given by

$$d_{C-H_{ethane}2sp^3HO} = d_{C-H_{ethane},H_2MO} - c' \tag{14.190}$$

Substitution of Eqs. (14.178) and (14.189) into Eq. (14.190) gives:

$$d_{C-H_{ethane}2sp^3HO} = 0.16189a_0 = 8.56687\ X\ 10^{-12}\ m \tag{14.191}$$

BOND ANGLE OF THE CH_3 GROUPS

Each CH_3 MO comprises a linear combination of three $C-H$-bond MOs. Each $C-H$-bond MO comprises the superposition of a H_2-type ellipsoidal MO and the $C_{ethane}2sp^3$ HO. A bond is also possible between the two H atoms of the $C-H$ bonds. Such $H-H$ bonding would decrease the $C-H$ bond strength since electron density would be shifted from the $C-H$ bonds to the $H-H$ bond. Thus, the bond angle between the two $C-H$ bonds is determined by the condition that the total energy of the H_2-type ellipsoidal MO between the terminal H atoms of the $C-H$ bonds is zero. From Eqs. (11.79) and (13.228), the distance from the origin to each focus of the $H-H$ ellipsoidal MO is:

$$c' = a\sqrt{\frac{\hbar^2 4\pi\varepsilon_0}{m_e e^2 2a}} = \sqrt{\frac{aa_0}{2}} \tag{14.192}$$

The internuclear distance from Eq. (13.229) is:

$$2c' = 2\sqrt{\frac{aa_0}{2}} \tag{14.193}$$

The length of the semiminor axis of the prolate spheroidal $H-H$ MO $b=c$ is given by Eq. (14.62).

The bond angle of the CH_3 groups of ethane is derived by using the orbital composition and an energy matching factor as in the case with the CH_3 radical. Since the two H_2-type ellipsoidal MOs initially comprise 75% of the H electron density of H_2 and the energy of each H_2-type ellipsoidal MO is matched to that of the $C_{ethane}2sp^3$ HO, the component energies and the total energy E_T of the $H-H$ bond are given by Eqs. (13.67-13.73) except that V_e, T, and V_m are corrected for the hybridization-energy-matching factor of 0.87495. Hybridization with 25% electron donation to the $C-C$-bond gives rise to the $C_{ethane}2sp^3$ HO-shell Coulombic energy $E_{Coulomb}\left(C_{ethane},2sp^3\right)$ given by Eq. (14.149). The corresponding normalization factor for determining the zero of the total $H-H$ bond energy is given by the ratio of $15.55033\,eV$, the magnitude of $E_{Coulomb}\left(C_{ethane},2sp^3\right)$ given by Eq. (14.149), and $13.605804\,eV$, the magnitude of the Coulombic energy between the electron and proton of H given by Eq. (1.264). The hybridization energy factor $C_{ethaneC2sp^3HO}$ is:

$$C_{ethaneC2sp^3HO} = \frac{\frac{e^2}{8\pi\varepsilon_0 a_0}}{\frac{e^2}{8\pi\varepsilon_0 r_{ethane2sp^3}}} = \frac{\frac{e^2}{8\pi\varepsilon_0 a_0}}{\frac{e^2}{8\pi\varepsilon_0 0.87495a_0}} = \frac{13.605804\ eV}{15.55033\ eV} = 0.87495 \tag{14.194}$$

Substitution of Eq. (14.152) into Eq. (13.233) with the hybridization factor of 0.87495 gives:

$$0 = \left[\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2}}}\left[\left(0.87495\right)^{-1}\left(\frac{3}{2}-\frac{3}{8}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{2}}}{a-\sqrt{\frac{aa_0}{2}}}-1\right]\left[1+\sqrt{\frac{2\hbar\sqrt{\frac{0.75e^2}{4\pi\varepsilon_0 a^3}}}{m_e c^2}}\right]\right.$$
$$\left.+\hbar\sqrt{\frac{\frac{0.75e^2}{8\pi\varepsilon_0 a^3}-\frac{e^2}{8\pi\varepsilon_0\left(a+c'\right)^3}}{0.5m_p}}\right] \tag{14.195}$$

From the energy relationship given by Eq. (14.195) and the relationship between the axes given by Eqs. (14.192-14.193) and (14.62-14.63), the dimensions of the $H-H$ MO can be solved.

The most convenient way to solve Eq. (14.195) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is

$$a = 5.7000a_0 = 3.0163\ X\ 10^{-10}\ m \tag{14.196}$$

Substitution of Eq. (14.196) into Eq. (14.192) gives:

$$c' = 1.6882a_0 = 8.9335\ X\ 10^{-11}\ m \tag{14.197}$$

The internuclear distance given by multiplying Eq. (14.197) by two is:

$$2c' = 3.3764a_0 = 1.7867\ X\ 10^{-10}\ m \tag{14.198}$$

Substitution of Eqs. (14.196-14.197) into Eq. (14.62) gives:

$$b = c = 5.4443a_0 = 2.8810\ X\ 10^{-10}\ m \tag{14.199}$$

Substitution of Eqs. (14.196-14.197) into Eq. (13.63) gives:

$$e = 0.2962 \tag{14.200}$$

From, $2c'_{H-H}$ (Eq. (14.198)), the distance between the two H atoms when the total energy of the corresponding MO is zero (Eq. (14.195)), and $2c'_{C-H}$ (Eq. (14.179)), the internuclear distance of each $C-H$ bond, the corresponding bond angle can be determined from the law of cosines. Using, Eq. (13.242), the bond angle θ between the $C-H$ bonds is

$$\theta = \cos^{-1}\left(\frac{2\left(2.09424\right)^2 - \left(3.3764\right)^2}{2\left(2.09424\right)^2}\right) = \cos^{-1}\left(-0.29964\right) = 107.44° \tag{14.201}$$

The experimental angle between the $C-H$ bonds is [8]:

$$\theta = 107.4° \tag{14.202}$$

The CH_3 radical has a pyramidal structure with the carbon atom along the z-axis at the apex and the hydrogen atoms at the base in the xy-plane. The distance $d_{origin-H}$ from the origin to the nucleus of a hydrogen atom given by Eqs. (14.198) and (13.412) is:

$$d_{origin-H} = 1.94936a_0 \tag{14.203}$$

The height along the z-axis of the pyramid from the origin to C nucleus d_{height} given by Eqs. (13.414), (14.179), and (14.203) is

$$d_{height} = 0.76540a_0 \tag{14.204}$$

The angle θ_v of each $C-H$ bond from the z-axis given by Eqs. (13.416), (14.203), and (14.204) is:

$$\theta_v = 68.563° \tag{14.205}$$

The $C-C$ bond is along the z-axis. Thus, the bond angle θ_{C-C-H} between the internuclear axis of the $C-C$ bond and a H atom of the methyl groups is given by:

$$\theta_{C-C-H} = 180 - \theta_v \tag{14.206}$$

Substitution of Eq. (14.205) into Eq. (14.206) gives:

$$\theta_{C-C-H} = 111.44° \tag{14.207}$$

The experimental angle between the $C-C-H$ bonds is [3]:

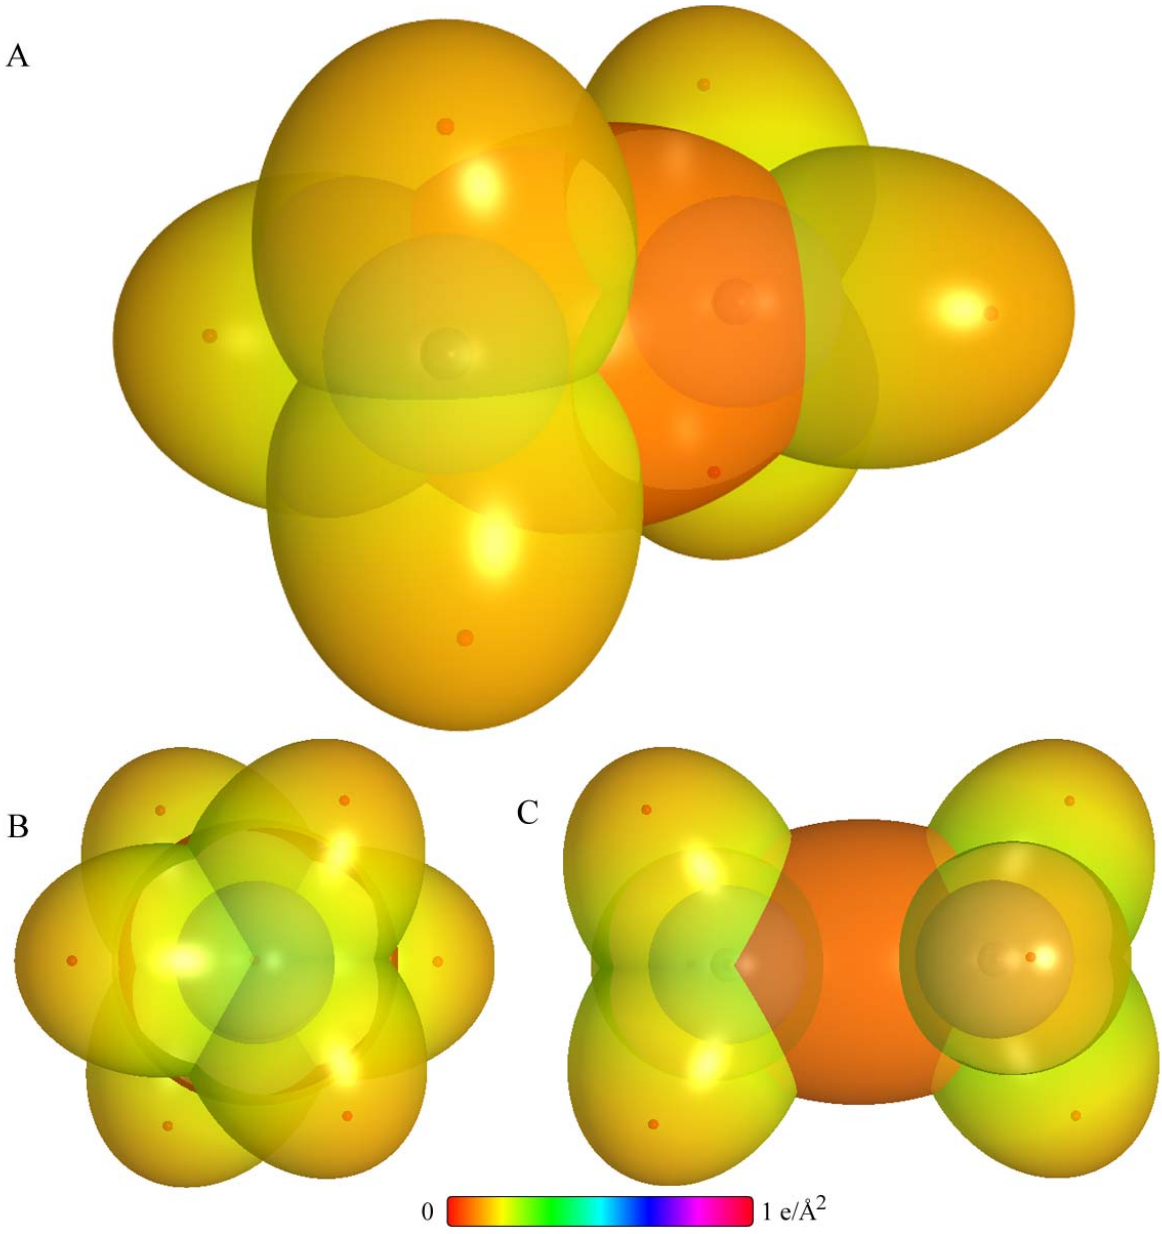
$$\theta_{C-C-H} = 111.17° \tag{14.208}$$

The CH_3CH_3 MO shown in Figure 14.7 was rendered using these parameters. A minimum energy is obtained with a staggered configuration consistent with observations [3].

The charge-density in the $C-C$-bond MO is increased by a factor of 0.25 with the formation of the $C_{ethane}2sp^3$ HOs each having a smaller radius. Using the orbital composition of the CH_3 groups (Eq. (14.173)) and the $C-C$-bond MO (Eq. (14.139)), the radii of $C1s = 0.17113a_0$ (Eq. (10.51)) and $C_{ethane}2sp^3 = 0.87495a_0$ (Eq. (14.148)) shells, and the parameters of the $C-C$-bond (Eqs. (13.3-13.4), (14.158-14.160), and (14.162-14.172)), the parameters of the $C-H$-bond MOs (Eqs. (13.3-13.4), (14.177-14.179), and (14.181-14.191)), and the bond-angle parameters (Eqs. (14.195-14.208)), the charge-density of the CH_3CH_3 MO comprising the linear combination of two sets of three $C-H$-bond MOs and a $C-C$-bond MO bridging the two methyl groups is shown in Figure 14.7. Each $C-H$-bond MO comprises a H_2-type ellipsoidal MO and a $C_{ethane}2sp^3$ HO

having the dimensional diagram shown in Figure 14.6. The $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{ethane}2sp^3$ HOs having the dimensional diagram shown in Figure 14.5.

Figure 14.7. CH_3CH_3 MO comprising the linear combination of two sets of three $C-H$-bond MOs and a $C-C$-bond MO. (A) Color scale, translucent view of the charge-density of the $C-C$-bond MO with the $C_{ethane}2sp^3$ HOs shown transparently. The $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{ethane}2sp^3$ HOs. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C_{ethane}2sp^3$ HO, the $C_{ethane}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown. (B)-(C) End-on view, translucent view high-lighting the $C-C$-bond MO, and opaque view of the charge-density of the CH_3CH_3 MO, respectively.



ENERGIES OF THE CH_3 GROUPS

The energies of each CH_3 group of ethane are given by the substitution of the semiprincipal axes (Eqs. (14.177-14.178) and (14.181)) into the energy equations of the methyl radical (Eqs. (13.556-13.560)), with the exception that $E\left(C_{ethane}, 2sp^3\right)$ replaces $E\left(C, 2sp^3\right)$ in Eq. (13.560):

$$V_e = 3\left(0.91771\right)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -107.68424\ eV \tag{14.209}$$

$$V_p = \frac{3e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 38.98068\ eV \tag{14.210}$$

$$T = 3\left(0.91771\right)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 32.73700\ eV \tag{14.211}$$

$$V_m = 3\left(0.91771\right)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -16.36850\ eV \tag{14.212}$$

$$E_{T_{ethane}}\left(CH_3\right) = -\frac{3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right] - 15.35946\ eV = -67.69451\ eV \tag{14.213}$$

where $E_{T_{ethane}}\left(CH_3\right)$ is given by Eq. (14.174) which is reiteratively matched to Eq. (13.542) within five-significant-figure round off error.

VIBRATION OF THE $^{12}CH_3$ GROUPS

The vibrational energy levels of CH_3 in ethane may be solved as three equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

THE DOPPLER ENERGY TERMS OF THE $^{12}CH_3$ GROUPS

The equations of the radiation reaction force of the methyl groups in ethane are the same as those of the methyl radical with the substitution of the methyl-group parameters. Using Eq. (13.561), the angular frequency of the reentrant oscillation in the transition state is

$$\omega = \sqrt{\frac{0.75e^2}{4\pi\varepsilon_0 b^3}} = 2.50664\ X\ 10^{16}\ rad/s \tag{14.214}$$

where b is given by Eq. (14.181). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)):

$$\overline{E}_K = \hbar\omega = \hbar 2.50664\ X\ 10^{16}\ rad/s = 16.49915\ eV \tag{14.215}$$

In Eq. (11.181), substitution of $E_T\left(H_2\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each H_2-type MO, for E_{hv}, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.215) for $\overline{E}_K$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$\overline{E}_D \cong E_{hv}\sqrt{\frac{2\overline{E}_K}{Mc^2}} = -31.63537\ eV\sqrt{\frac{2e\left(16.49915\ eV\right)}{m_e c^2}} = -0.25422\ eV \tag{14.216}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of CH_3 due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\overline{E}_{osc}$, is given by the sum of the corresponding energies, $\overline{E}_D$ given by Eq. (14.216) and $\overline{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of each $C-H$ bond. Using ω_e given by Eq. (13.458) for $\overline{E}_{Kvib}$ of the transition state having three independent bonds, $\overline{E}'_{ethane\ osc}\left(^{12}CH_3\right)$ per bond is:

$$\overline{E}'_{ethane\ osc}\left(^{12}CH_3\right) = \overline{E}_D + \overline{E}_{Kvib} = \overline{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{14.217}$$

$$\overline{E}'_{ethane\ osc}\left(^{12}CH_3\right) = -0.25422\ eV + \frac{1}{2}\left(0.35532\ eV\right) = -0.07656\ eV \tag{14.218}$$

Given that the vibration and reentrant oscillation is for three $C-H$ bonds, $\bar{E}_{ethane\ osc}\left({}^{12}CH_3\right)$, is:

$$\bar{E}_{ethane\ osc}\left({}^{12}CH_3\right)=3\left(\bar{E}_D+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)=3\left(-0.25422\ eV+\frac{1}{2}\left(0.35532\ eV\right)\right)=-0.22967\ eV \tag{14.219}$$

TOTAL AND DIFFERENCE ENERGIES OF THE ${}^{12}CH_3$ GROUPS

$E_{ethaneT+osc}\left({}^{12}CH_3\right)$, the total energy of each ${}^{12}CH_3$ group including the Doppler term, is given by the sum of $E_{T_{ethane}}\left(CH_3\right)$ (Eq. (14.213)) and $\bar{E}_{ethane\ osc}\left({}^{12}CH_3\right)$ given by Eq. (14.219).

$$\begin{aligned}E_{ethaneT+osc}\left({}^{12}CH_3\right)&=V_e+T+V_m+V_p+E\left(C_{ethane},2sp^3\right)+\bar{E}_{ethane\ osc}\left({}^{12}CH_3\right)\\&=E_{T_{ethane}}\left(CH_3\right)+\bar{E}_{ethane\ osc}\left({}^{12}CH_3\right)\end{aligned} \tag{14.220}$$

$$E_{ethaneT+osc}\left({}^{12}CH_3\right)=\left\{\begin{array}{l}\left(\frac{-3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-15.359469\ eV\right)\\-3\left(\left(31.63536831\ eV\right)\sqrt{\frac{2\hbar\sqrt{\frac{3}{4}\frac{e^2}{4\pi\varepsilon_0 b^3}}}{m_e c^2}}-\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)\end{array}\right\} \tag{14.221}$$

$$=-67.69450\ eV-3\left(0.25422\ eV-\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)$$

From Eqs. (14.217-14.221), the total energy of each ${}^{12}CH_3$ is:

$$\begin{aligned}E_{ethaneT+osc}\left({}^{12}CH_3\right)&=-67.69450\ eV+\bar{E}_{ethane\ osc}\left({}^{12}CH_3\right)\\&=-67.69450\ eV-3\left(0.25422\ eV-\frac{1}{2}\left(0.35532\ eV\right)\right)=-67.92417\ eV\end{aligned} \tag{14.222}$$

where ω_e given by Eq. (13.458) was used for the $\hbar\sqrt{\frac{k}{\mu}}$ term.

The total energy for each methyl radical given by Eq. (13.569) is:

$$\begin{aligned}E_{radicalT+osc}\left({}^{12}CH_3\right)&=-67.69450\ eV+\bar{E}_{radical\ osc}\left({}^{12}CH_3\right)\\&=-67.69450\ eV-3\left(0.25670\ eV-\frac{1}{2}\left(0.35532\ eV\right)\right)=-67.93160\ eV\end{aligned} \tag{14.223}$$

The difference in energy between the methyl groups and the methyl radical $\Delta E_{T+osc}\left({}^{12}CH_3\right)$ is given by two times the difference between Eqs. (14.222) and (14.223):

$$\begin{aligned}\Delta E_{T+osc}\left({}^{12}CH_3\right)&=2\left(E_{ethaneT+osc}\left({}^{12}CH_3\right)-E_{radicalT+osc}\left({}^{12}CH_3\right)\right)\\&=2\left(-67.92417\ eV-\left(-67.93160\ eV\right)\right)=0.01487\ eV\end{aligned} \tag{14.224}$$

SUM OF THE ENERGIES OF THE $C-C$ σ MO AND THE HOS OF ETHANE

The energy components of V_e, V_p, T, V_m, and E_T of the $C-C$-bond MO are the same as those of the CH MO as well as each $C-H$-bond MO of the methyl groups except that energy of the $C_{ethane}2sp^3$ HO is used. The energies of each $C-C$-bond MO are given by the substitution of the semiprincipal axes (Eqs. (14.158-14.159) and (14.162)) into the energy equations of the CH MO (Eqs. (13.449-13.453)), with the exception that $E\left(C_{ethane},2sp^3\right)$ replaces $E\left(C,2sp^3\right)$ in Eq. (13.453).

$$V_e=\left(0.91771\right)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=-29.101124\ eV \tag{14.225}$$

$$V_p=\frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}=9.37273\ eV \tag{14.226}$$

$$T=\left(0.91771\right)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=6.90500\ eV \tag{14.227}$$

$$V_m = (0.91771)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -3.45250\ eV \tag{14.228}$$

$$E_T(C-C,\sigma) = -\frac{e^2}{8\pi\varepsilon_0 c'}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-15.35946\ eV = -31.63535\ eV \tag{14.229}$$

where $E_T(C-C,\sigma)$ is the total energy of the $C-C$ σ MO given by Eq. (14.155) which is reiteratively matched to Eq. (13.75) within five-significant-figure round off error.

The total energy of the $C-C$-bond MO, $E_T(C-C)$, is given by the sum of two times $E_T(C-C,2sp^3)$, the energy change of each $C2sp^3$ shell due to the decrease in radius with the formation of the $C-C$-bond MO (Eq. (14.151)), and $E_T(C-C,\sigma)$, the σ MO contribution given by Eq. (14.156).

$$\begin{aligned} E_T(C-C) &= 2E_T(C-C,2sp^3)+E_T(C-C,\sigma) \\ &= \left(\begin{array}{l} 2(-0.72457\ eV)+ \\ \left(-\frac{e^2}{8\pi\varepsilon_0\sqrt{aa_0}}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{aa_0}}{a-\sqrt{aa_0}}-1\right]-15.35946\ eV\right) \end{array}\right) \\ &= 2(-0.72457\ eV)+(-31.63537\ eV) = -33.08452\ eV \end{aligned} \tag{14.230}$$

VIBRATION OF ETHANE

The vibrational energy levels of CH_3CH_3 may be solved as two sets of three equivalent coupled harmonic oscillators with a bridging harmonic oscillator by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

THE DOPPLER ENERGY TERMS OF THE $C-C$-BOND MO OF ETHANE

The equations of the radiation reaction force of the symmetrical $C-C$-bond MO are given by Eqs. (11.231-11.233), except the force-constant factor is 0.5 based on the force constant k' of Eq. (14.152), and the $C-C$-bond MO parameters are used. The angular frequency of the reentrant oscillation in the transition state is

$$\omega = \sqrt{\frac{\frac{0.5e^2}{4\pi\varepsilon_0 a^3}}{m_e}} = 9.55643\ X\ 10^{15}\ rad/s \tag{14.231}$$

where a is given by Eq. (14.158). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K = \hbar\omega = \hbar 9.55643\ X\ 10^{15}\ rad/s = 6.29021\ eV \tag{14.232}$$

In Eq. (11.181), substitution of $E_T(C-C)$ (Eq. (14.230)) for E_{hv}, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.232) for $\bar{E}_K$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$\bar{E}_D \cong E_{hv}\sqrt{\frac{2\bar{E}_K}{Mc^2}} = -33.08450\ eV\sqrt{\frac{2e(6.29021\ eV)}{m_e c^2}} = -0.16416\ eV \tag{14.233}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $C-C$-bond MO due to the reentrant orbit of the bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (14.233) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of the $C-C$ bond. Using the experimental $C-C$ $E_{vib}(\upsilon_3)$ of 993 cm^{-1} $(0.12312\ eV)$ [10] for $\bar{E}_{Kvib}$ of the transition state, $\bar{E}_{osc}(C-C,\sigma)$ is:

$$\bar{E}_{osc}(C-C,\sigma) = \bar{E}_D + \bar{E}_{Kvib} = \bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{14.234}$$

$$\bar{E}_{osc}(C-C,\sigma) = -0.16416\ eV + \frac{1}{2}(0.12312\ eV) = -0.10260\ eV \tag{14.235}$$

TOTAL ENERGIES OF THE $C-C$-BOND MO OF ETHANE

$E_{T+osc}\left(C-C\right)$, the total energy of the $C-C$-bond MO including the Doppler term, is given by the sum of $E_T\left(C-C\right)$ (Eq. (14.230)) and $\bar{E}_{osc}\left(C-C,\sigma\right)$ given by Eq. (14.235).

$$\begin{aligned} E_{T+osc}\left(C-C\right) &= V_e+T+V_m+V_p+E\left(C_{ethane},2sp^3\right)+2E_T\left(C-C,2sp^3\right)+\bar{E}_{osc}\left(C-C,\sigma\right) \\ &= E_T\left(C-C,\sigma\right)+2E_T\left(C-C,2sp^3\right)+\bar{E}_{osc}\left(C-C,\sigma\right)=E_T\left(C-C\right)+\bar{E}_{osc}\left(C-C,\sigma\right) \end{aligned} \tag{14.236}$$

$$\begin{aligned} E_{T+osc}\left(C-C\right) &= \left\{\begin{array}{l}\left(\frac{-e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-15.35946\ eV+2E_T\left(C-C,2sp^3\right)\right) \\ \left(1+\sqrt{\frac{2\hbar\sqrt{\frac{1}{2}\frac{e^2}{4\pi\varepsilon_0 a^3}}}{m_e c^2}}\right)+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\end{array}\right\} \\ &= -33.08452\ eV-0.16416\ eV+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \end{aligned} \tag{14.237}$$

From Eqs. (14.234-14.237), the total energy of the $C-C$-bond MO is:

$$\begin{aligned} E_{T+osc}\left(C-C\right) &= -31.63537\ eV+2E_T\left(C-C,2sp^3\right)+\bar{E}_{osc}\left(C-C,\sigma\right) \\ &= -31.63537\ eV+2\left(-0.72457\ eV\right)-0.16416\ eV+\frac{1}{2}\left(0.12312\ eV\right)=-33.18712\ eV \end{aligned} \tag{14.238}$$

where the experimental E_{vib} was used for the $\hbar\sqrt{\frac{k}{\mu}}$ term.

BOND ENERGY OF THE $C-C$ BOND OF ETHANE

The dissociation energy of the $C-C$ bond of CH_3CH_3, $E_D\left(H_3C-CH_3\right)$, is given by two times $E\left(C,2sp^3\right)$ (Eq. (14.146)), the initial energy of the $C2sp^3$ HO of each CH_3 radical that bond with a single $C-C$ bond, minus the sum of $\Delta E_{T+osc}\left({}^{12}CH_3\right)$ (Eq. (14.224)), the energy change going from the methyl radicals to the methyl groups of ethane, and $E_{T+osc}\left(C-C\right)$ (Eq. (14.238)). Thus, the dissociation energy of the $C-C$ bond of CH_3CH_3, is:

$$\begin{aligned} E_D\left(H_3C-CH_3\right) &= 2\left(E\left(C,2sp^3\right)\right)-\left(\Delta E_{T+osc}\left({}^{12}CH_3\right)+E_{T+osc}\left(C-C\right)\right) \\ &= 2\left(-14.63489\ eV\right)-\left(0.01487\ eV-33.18712\ eV\right) \\ &= 2\left(-14.63489\ eV\right)-\left(33.17225\ eV\right)=3.90247\ eV \end{aligned} \tag{14.239}$$

The experimental dissociation energy of the $C-C$ bond of CH_3CH_3 is [6]:

$$E_D\left(H_3C-CH_3\right)=3.89690\ eV \tag{14.240}$$

The results of the determination of bond parameters of CH_3CH_3 are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

ETHYLENE MOLECULE (CH_2CH_2)

The ethylene molecule CH_2CH_2 is formed by the reaction of two dihydrogen carbide radicals:

$$CH_2+CH_2\rightarrow CH_2CH_2 \tag{14.241}$$

CH_2CH_2 can be solved using the same principles as those used to solve the methane series $CH_{n=1,2,3,4}$, wherein the $2s$ and $2p$ shells of each C hybridize to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. First, two sets of two H atomic orbitals (AOs) combine with two sets of two carbon $2sp^3$ HOs to form two dihydrogen carbide groups comprising a linear combination of four diatomic H_2-type MOs developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section. Then, the two CH_2 groups bond by forming a H_2-type MO between the remaining two $C2sp^3$ HOs on each carbon atom.

FORCE BALANCE OF THE $C=C$-BOND MO OF ETHYLENE

CH_2CH_2 comprises a chemical bond between two CH_2 radicals wherein each radical comprises two chemical bonds between carbon and hydrogen atoms. The solution of the parameters of CH_2 is given in the Dihydrogen Carbide (CH_2) section. Each $C-H$ bond of CH_2 having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of 75% H_2-type ellipsoidal MO and 25% $C2sp^3$ HO. The proton of the H atom and the nucleus of the C atom are along each internuclear axis and serve as the foci. As in the case of H_2, each of the two $C-H$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $C2sp^3$ HO for distances shorter than the radius of the $C2sp^3$ shell since it is energetically unfavorable. Thus, each MO surface comprises a prolate spheroid at the H proton that is continuous with the $C2sp^3$ shell at the C atom whose nucleus serves as the other focus. The electron configuration and the energy, $E\left(C,2sp^3\right)$, of the $C2sp^3$ shell is given by Eqs. (13.422) and (13.428), respectively. The central paramagnetic force due to spin of each $C-H$ bond is provided by the spin-pairing force of the CH_2 MO that has the symmetry of an s orbital that superimposes with the $C2sp^3$ orbitals such that the corresponding angular momenta are unchanged.

Two CH_2 radicals bond to form CH_2CH_2 by forming a MO between the two pairs of remaining $C2sp^3$-HO electrons of the two carbon atoms. However, in this case, the sharing of electrons between four $C2sp^3$ HOs to form a molecular orbital (MO) comprising four spin-paired electrons permits each $C2sp^3$ HO to decrease in radius and energy.

As in the case of the $C-H$ bonds, the $C=C$-bond MO is a prolate-spheroidal-MO surface that cannot extend into $C2sp^3$ HO for distances shorter than the radius of the $C2sp^3$ shell of each atom. Thus, the MO surface comprises a partial prolate spheroid in between the carbon nuclei and is continuous with the $C2sp^3$ shell at each C atom. The energy of the H_2-type ellipsoidal MO is matched to that of the $C2sp^3$ shell. As in the case of previous examples of energy-matched MOs such as those of OH, NH, CH, the $C=O$-bond MO of CO_2, and the $C-C$-bond MO of CH_3CH_3, the $C=C$-bond MO of ethylene must comprise 75% of a H_2-type ellipsoidal MO in order to match potential, kinetic, and orbital energy relationships. Thus, the $C=C$-bond MO must comprise a linear combination of two MOs wherein each comprises two $C2sp^3$ HOs and 75% of a H_2-type ellipsoidal MO divided between the $C2sp^3$ HOs:

$$2\left(2\ C2sp^3+0.75\ H_2\ MO\right)\rightarrow C=C-bond\ MO \tag{14.242}$$

The linear combination of each H_2-type ellipsoidal MO with each $C2sp^3$ HO further comprises an excess 25% charge-density contribution from each $C2sp^3$ HO to the $C=C$-bond MO to achieve an energy minimum. The force balance of the $C=C$-bond MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.242) and the energy matching condition between the $C2sp^3$-HO components of the MO.

Similarly, the energies of each CH_2 MO involve each $C2sp^3$ and each $H1s$ electron with the formation of each $C-H$ bond. The sum of the energies of the H_2-type ellipsoidal MOs is matched to that of the $C2sp^3$ shell. This energy is determined by the considering the effect of the donation of 25% electron density from the two pairs of $C2sp^3$ HOs to the $C=C$-bond MO with the formation of the $C_{ethylene}2sp^3$ HOs each having a smaller radius. The $2sp^3$ hybridized orbital arrangement is given by Eq. (14.140). The sum $E_T\left(C,2sp^3\right)$ of calculated energies of C, C^+, C^{2+}, and C^{3+} is given by Eq. (14.141). The radius r_{2sp^3} of the $C2sp^3$ shell is given by Eq. (14.142). The Coulombic energy $E_{Coulomb}\left(C,2sp^3\right)$ and the energy $E\left(C,2sp^3\right)$ of the outer electron of the $C2sp^3$ shell are given by Eqs. (14.143) and (14.146), respectively.

Next, consider the formation of the $C=C$-bond MO of ethylene from two CH_2 radicals, each having a $C2sp^3$ electron with an energy given by Eq. (14.146). The total energy of the state is given by the sum over the four electrons. The sum $E_T\left(C_{ethylene},2sp^3\right)$ of calculated energies of $C2sp^3$, C^+, C^{2+}, and C^{3+} from Eqs. (10.123), (10.113-10.114), (10.68), and (10.48), respectively, is:

$$\begin{aligned}E_T\left(C_{ethylene},2sp^3\right)&=-\left(64.3921\ eV+48.3125\ eV+24.2762\ eV+E\left(C,2sp^3\right)\right)\\&=-\left(64.3921\ eV+48.3125\ eV+24.2762\ eV+14.63489\ eV\right)\\&=-151.61569\ eV\end{aligned} \tag{14.243}$$

where $E\left(C,2sp^3\right)$ (Eq. (14.146)) is the sum of the energy of C, $-11.27671\,eV$, and the hybridization energy. The orbital-angular-momentum interactions also cancel such that the energy of the $E_T\left(C_{ethylene},2sp^3\right)$ is purely Coulombic.

The sharing of electrons between two pairs of $C2sp^3$ HOs to form a $C=C$-bond MO permits each participating hybridized orbital to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each participating $C2sp^3$ HO donates an excess of 25% per bond of its electron density to the $C=C$-bond MO to form an energy minimum. By considering this electron redistribution in the ethylene molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{ethylene\,2sp^3}$ of the $C2sp^3$ shell of ethylene may be calculated from the Coulombic energy using Eq. (10.102).

$$r_{ethylene\,2sp^3}=\left(\sum_{n=2}^{5}(Z-n)-0.5\right)\frac{e^2}{8\pi\varepsilon_0\left(e151.61569\ eV\right)}=\frac{9.5e^2}{8\pi\varepsilon_0\left(e151.61569\ eV\right)}=0.85252a_0 \tag{14.244}$$

where $Z=6$ for carbon. Using Eqs. (10.102) and (14.244), the Coulombic energy $E_{Coulomb}\left(C_{ethylene},2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is:

$$E_{Coulomb}\left(C_{ethylene},2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{ethylene\,2sp^3}}=\frac{-e^2}{8\pi\varepsilon_0 0.85252a_0}=-15.95955\ eV \tag{14.245}$$

During hybridization, the spin-paired $2s$ electrons are promoted to the $C2sp^3$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (13.152). Using Eqs. (14.145) and (14.245), the energy $E\left(C_{ethylene},2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is

$$E\left(C_{ethylene},2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{ethylene\,2sp^3}}+\frac{2\pi\mu_0 e^2\hbar^2}{m_e^2\left(r_3\right)^3}=-15.95955\ eV+0.19086\ eV=-15.76868\ eV \tag{14.246}$$

Thus, $E_T\left(C=C,2sp^3\right)$, the energy change of each $C2sp^3$ shell with the formation of the $C=C$-bond MO is given by the difference between Eq. (14.146) and Eq. (14.246):

$$E_T\left(C=C,2sp^3\right)=E\left(C_{ethylene},2sp^3\right)-E\left(C,2sp^3\right)=-15.76868\ eV-\left(-14.63489\ eV\right)=-1.13380\ eV \tag{14.247}$$

As in the case of Cl_2, each H_2-type ellipsoidal MO comprises 75% of the $C=C$-bond MO shared between two $C2sp^3$ HOs corresponding to the electron charge density in Eq. (11.65) of $\frac{-0.75e}{2}$. But, the additional 25% charge-density contribution to each bond of the $C=C$-bond MO causes the electron charge density in Eq. (11.65) to be $\frac{-e}{2}=-0.5e$. The corresponding force constant k' is given by Eq. (14.152). In addition, the energy matching at both $C2sp^3$ HOs further requires that k' be corrected by the hybridization factor given by Eq. (13.430). Thus, the force constant k' to determine the ellipsoidal parameter c' in terms of the central force of the foci (Eq. (11.65)) is given by:

$$k'=C_{C2sp^3HO}\frac{(0.5)2e^2}{4\pi\varepsilon_0}=0.91771\frac{(0.5)2e^2}{4\pi\varepsilon_0} \tag{14.248}$$

The distance from the origin to each focus c' is given by substitution of Eq. (14.248) into Eq. (13.60). Thus, the distance from the origin of the component of the double $C=C$-bond MO to each focus c' is given by:

$$c'=a\sqrt{\frac{\hbar^2 4\pi\varepsilon_0}{(0.91771)m_e e^2 a}}=\sqrt{\frac{aa_0}{0.91771}} \tag{14.249}$$

The internuclear distance from Eq. (14.249) is:

$$2c'=2\sqrt{\frac{aa_0}{0.91771}} \tag{14.250}$$

The length of the semiminor axis of the prolate spheroidal $C=C$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of the $C=C$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the $C=C$-bond MO are solved.

The general equations for the energy components of V_e, V_p, T, V_m, and E_T of the $C=C$-bond MO are the same as those of the CH MO except that energy of the $C_{ethylene}2sp^3$ HO is used and the double-bond nature is considered. In the case of a single bond, the prolate spheroidal H_2-type MO transitions to the $C_{ethylene}2sp^3$ HO of each carbon, and the energy of the $C_{ethylene}2sp^3$ shell must remain constant and equal to the $E\left(C_{ethylene},2sp^3\right)$ given by Eq. (14.246). Thus, the energy $E\left(C_{ethylene},2sp^3\right)$ in Eq. (14.246) adds to that of the energies of the corresponding H_2-type ellipsoidal MO. The second bond of the double $C=C$-bond MO also transitions to the $C_{ethylene}2sp^3$ HO of each C. The energy of a second H_2-type ellipsoidal MO

adds to the first energy component, and the two bonds achieve an energy minimum as a linear combination of the two H_2-type ellipsoidal MOs each having the carbon nuclei as the foci. Each $C-C$-bond MO comprises the same $C_{ethylene}2sp^3$ HO shells of constant energy given by Eq. (14.246). As in the case of the water, NH_2, and ammonia molecules given by Eqs. (13.180), (13.320), and (13.372), respectively, the energy of the redundant shell is subtracted from the total energy of the linear combination of the σ MO. Thus, the total energy $E_T\left(C=C,\sigma\right)$ of the σ component of the $C=C$-bond MO is given by the sum of the energies of the two bonds each comprising the linear combination of the $C_{ethylene}2sp^3$ HO and the H_2-type ellipsoidal MO as given by Eq. (14.242) wherein the E_T terms add positively, the $E\left(C_{ethylene},2sp^3\right)$ terms cancel, and the energy matching condition between the components is provided by Eq. (14.248). Using Eqs. (13.431) and (14.246), $E_T\left(C=C,\sigma\right)$ is given by:

$$\begin{aligned} E_T\left(C=C,\sigma\right) &= E_T + E\left(C_{ethylene},2sp^3\right) - E\left(C_{ethylene},2sp^3\right) \\ &= -\frac{2e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right] \end{aligned} \tag{14.251}$$

The total energy term of the double $C=C$-bond MO is given by the sum of the two H_2-type ellipsoidal MOs given by Eq. (11.212). To match this boundary condition, $E_T\left(C=C,\sigma\right)$ given by Eq. (14.251) is set equal to two times Eq. (13.75).

$$E_T\left(C=C,\sigma\right) = -\frac{2e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right] = -63.27074\ eV \tag{14.252}$$

From the energy relationship given by Eq. (14.252) and the relationship between the axes given by Eqs. (14.249-14.250) and (13.62-13.63), the dimensions of the $C=C$-bond MO can be solved.

Substitution of Eq. (14.249) into Eq. (14.252) gives:

$$\frac{2e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{0.91771}}}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{0.91771}}}{a-\sqrt{\frac{aa_0}{0.91771}}}-1\right] = e63.27074 \tag{14.253}$$

The most convenient way to solve Eq. (14.253) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a = 1.47228a_0 = 7.79098\ X\ 10^{-11}\ m \tag{14.254}$$

Substitution of Eq. (14.254) into Eq. (14.249) gives

$$c' = 1.26661a_0 = 6.70259\ X\ 10^{-11}\ m \tag{14.255}$$

The internuclear distance given by multiplying Eq. (14.255) by two is:

$$2c' = 2.53321a_0 = 1.34052\ X\ 10^{-10}\ m \tag{14.256}$$

The experimental bond distance is [3]:

$$2c' = 1.339\ X\ 10^{-10}\ m \tag{14.257}$$

Substitution of Eqs. (14.254-14.255) into Eq. (13.62) gives:

$$b = c = 0.75055a_0 = 3.97173\ X\ 10^{-11}\ m \tag{14.258}$$

Substitution of Eqs. (14.252-14.255) into Eq. (13.63) gives:

$$e = 0.86030 \tag{14.259}$$

The nucleus of the C atoms comprise the foci of the H_2-type ellipsoidal MO. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $C_{ethylene}2sp^3$ HO are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where $r_n = r_{ethylene2sp^3} = 0.85252a_0$ is the radius of the $C_{ethylene}2sp^3$ shell. Substitution of Eqs. (14.254-14.255) into Eq. (13.261) gives:

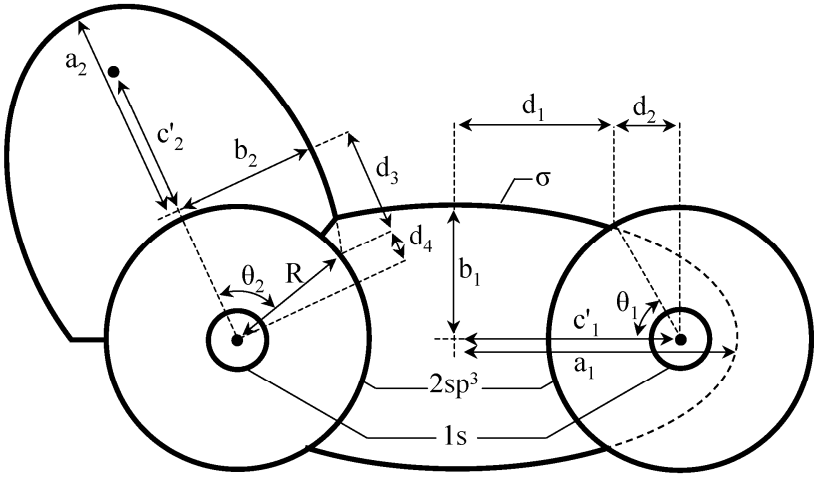
$$\theta' = 129.84° \tag{14.260}$$

Then, the angle $\theta_{C=C_{ethylene}2sp^3HO}$ the radial vector of the $C2sp^3$ HO makes with the internuclear axis is:

$$\theta_{C=C_{ethylene}2sp^3HO} = 180° - 129.84° = 50.16° \tag{14.261}$$

as shown in Figure 14.8.

Figure 14.8. The cross section of the $C=C$-bond MO (σ MO) and one $C-H$-bond MO of ethylene showing the axes, angles, and point of intersection of each H_2-type ellipsoidal MO with the corresponding $C_{ethylene}2sp^3$ HO. The continuation of each H_2-type-ellipsoidal-MO basis element of the $C=C$ bond and the $C-H$-bond beyond the intersection point with each $C_{ethylene}2sp^3$ shell and σ MO is shown as dashed since each only serves to solve the energy match with the $C_{ethylene}2sp^3$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of each intersection point. The actual charge density is shown by the solid lines. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, $d_1 : d_{C=C_{ethylene},H_2MO}$, $\theta_1 : \theta_{C=C_{ethylene}2sp^3HO}$, $d_2 : d_{C=C_{ethylene}2sp^3HO}$, $R : r_{ethyleneC2sp^3}$, $d_3 : d_{C-H_{ethylene},H_2MO}$, $\theta_2 : \theta_{C-H_{ethylene}2sp^3HO}$, and $d_4 : d_{C-H_{ethylene}2sp^3HO}$.



Consider the right-hand intersection point. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{C=C_{ethylene},H_2MO}$ satisfies the following relationship:

$$r_{ethylene2sp^3} \sin\theta_{C=C_{ethylene}2sp^3HO} = 0.85252a_0 \sin\theta_{C=C_{ethylene}2sp^3HO} = b\sin\theta_{C=C_{ethylene},H_2MO} \tag{14.262}$$

such that

$$\theta_{C=C_{ethylene},H_2MO} = \sin^{-1}\frac{0.85252a_0 \sin\theta_{C=C_{ethylene}2sp^3HO}}{b} = \sin^{-1}\frac{0.85252a_0 \sin 50.16°}{b} \tag{14.263}$$

with the use of Eq. (14.261). Substitution of Eq. (14.258) into Eq. (14.263) gives:

$$\theta_{C=C_{ethylene},H_2MO} = 60.70° \tag{14.264}$$

Then, the distance $d_{C=C_{ethylene},H_2MO}$ along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$d_{C=C_{ethylene},H_2MO} = a\cos\theta_{C=C_{ethylene},H_2MO} \tag{14.265}$$

Substitution of Eqs. (14.254) and (14.264) into Eq. (14.265) gives:

$$d_{C=C_{ethylene},H_2MO} = 0.72040a_0 = 3.81221\ X\ 10^{-11}\ m \tag{14.266}$$

The distance $d_{C=C_{ethylene}2sp^3HO}$ along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals is given by:

$$d_{C=C_{ethylene}2sp^3HO} = c' - d_{C=C_{ethylene},H_2MO} \tag{14.267}$$

Substitution of Eqs. (14.255) and (14.266) into Eq. (14.267) gives:

$$d_{C=C_{ethylene}2sp^3HO} = 0.54620a_0 = 2.89038\ X\ 10^{-11}\ m \tag{14.268}$$

FORCE BALANCE OF THE CH_2 MOS OF ETHYLENE

Each of the two equivalent CH_2 MOs must comprise two $C-H$ bonds with each comprising 75% of a H_2-type ellipsoidal MO and a $C2sp^3$ HO as given by Eq. (13.494):

$$2\left[1\,C2sp^3+0.75\,H_2\;MO\right]\rightarrow CH_2\;MO \tag{14.269}$$

The force balance of the CH_2 MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.494) and the energy matching condition between the hydrogen and $C2sp^3$ HO components of the MO.

The force constant k' to determine the ellipsoidal parameter c' of each H_2-type-ellipsoidal-MO component of the CH_2 MO in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus c' is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $C-H$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the CH_2 MO are solved.

Consider the formation of the double $C=C$-bond MO of ethylene from two CH_2 radicals, each having a $C2sp^3$ shell with an energy given by Eq. (14.146). The energy components of V_e, V_p, T, V_m, and E_T are the same as those of the dihydrogen carbide radical, two times those of CH corresponding to the two $C-H$ bonds, except that two times $E_T\left(C=C,2sp^3\right)$ is subtracted from $E_T\left(CH_2\right)$ of Eq. (13.495). The subtraction of the energy change of the $C2sp^3$ shells with the formation of the $C=C$-bond MO matches the energy of the $C-H$-bond MOs to the decrease in the energy of the $C2sp^3$ HOs. Using Eqs. (13.495) and (14.247), $E_{T_{ethylene}}\left(CH_2\right)$ is given by:

$$E_{T_{ethylene}}\left(CH_2\right)=E_T+E\left(C,2sp^3\right)-2E_T\left(C=C,2sp^3\right)=\begin{pmatrix}-\dfrac{2e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+c'}{a-c'}-1\right]\\-14.63489\;eV-\left(-2.26758\;eV\right)\end{pmatrix} \tag{14.270}$$

$E_{T_{ethylene}}\left(CH_2\right)$ given by Eq. (14.270) is set equal to two times the energy of the H_2-type ellipsoidal MO minus the Coulombic energy of H given by Eq. (13.496):

$$E_{T_{ethylene}}\left(CH_2\right)=\begin{pmatrix}-\dfrac{2e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+c'}{a-c'}-1\right]\\-14.63489\;eV-\left(-2.26758\;eV\right)\end{pmatrix}=-49.66493\;eV \tag{14.271}$$

From the energy relationship given by Eq. (14.271) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the CH_2 MO can be solved.

Substitution of Eq. (13.60) into Eq. (14.271) gives:

$$\frac{2e^2}{8\pi\varepsilon_0\sqrt{\dfrac{2aa_0}{3}}}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\dfrac{2aa_0}{3}}}{a-\sqrt{\dfrac{2aa_0}{3}}}-1\right]=e37.29762 \tag{14.272}$$

The most convenient way to solve Eq. (14.272) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a=1.56946a_0=8.30521\;X\;10^{-11}\;m \tag{14.273}$$

Substitution of Eq. (14.273) into Eq. (13.60) gives:

$$c'=1.02289a_0=5.41290\;X\;10^{-11}\;m \tag{14.274}$$

The internuclear distance given by multiplying Eq. (14.274) by two is:

$$2c'=2.04578a_0=1.08258\;X\;10^{-10}\;m \tag{14.275}$$

The experimental bond distance is [3]:

$$2c'=1.087\;X\;10^{-10}\;m \tag{14.276}$$

Substitution of Eqs. (14.273-14.274) into Eq. (14.62) gives:

$$b=c=1.19033a_0=6.29897\;X\;10^{-11}\;m \tag{14.277}$$

Substitution of Eqs. (14.273-14.274) into Eq. (14.63) gives:

$$e=0.65175 \tag{14.278}$$

The nucleus of the H atom and the nucleus of the C atom comprise the foci of each H_2-type ellipsoidal MO. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $C_{ethylene}2sp^3$ HO are given by Eqs. (13.84-13.95)

and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where $r_n = r_{ethylene2sp^3} = 0.85252a_0$ is the radius of the $C_{ethylene}2sp^3$ shell. Substitution of Eqs. (14.273-14.274) into Eq. (13.261) gives:

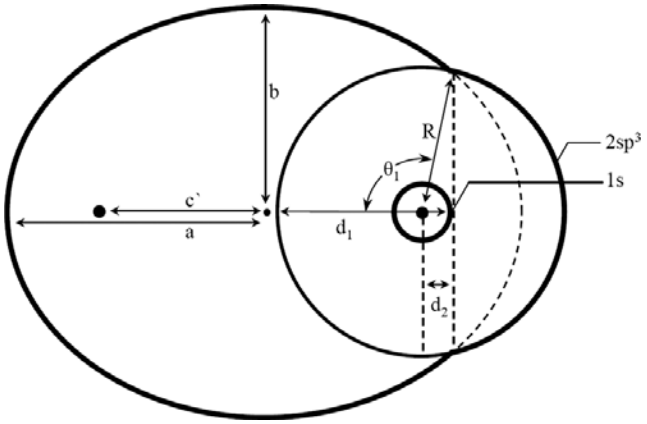
$$\theta' = 84.81° \tag{14.279}$$

Then, the angle $\theta_{C-H_{ethylene}2sp^3HO}$ the radial vector of the $C2sp^3$ HO makes with the internuclear axis is:

$$\theta_{C-H_{ethylene}2sp^3HO} = 180° - 84.81° = 95.19° \tag{14.280}$$

as shown in Figure 14.9.

Figure 14.9. The cross section of one $C-H$-bond MO of ethylene showing the axes, angles, and point of intersection of the H_2-type ellipsoidal MO with the $C_{ethylene}2sp^3$ HO. The continuation of the H_2-type-ellipsoidal-MO basis element beyond the intersection point with the $C_{ethylene}2sp^3$ shell is shown as dashed since it only serves to solve the energy match with the $C_{ethylene}2sp^3$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of the intersection point. The actual charge density is shown by the solid lines. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, $d_1 : d_{C-H_{ethylene},H_2MO}$, $\theta_1 : \theta_{C-H_{ethylene}2sp^3HO}$, $d_2 : d_{C-H_{ethylene}2sp^3HO}$, and $R : r_{ethylene2sp^3}$.



The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{C-H_{ethylene},H_2MO}$ satisfies the following relationship:

$$r_{ethylene2sp^3} \sin\theta_{C-H_{ethylene}2sp^3HO} = 0.85252a_0 \sin\theta_{C-H_{ethylene}2sp^3HO} = b\sin\theta_{C-H,H_2MO} \tag{14.281}$$

such that

$$\theta_{C-H_{ethylene},H_2MO} = \sin^{-1}\frac{0.85252a_0 \sin\theta_{C-H_{ethylene}2sp^3HO}}{b} = \sin^{-1}\frac{0.85252a_0 \sin 95.19°}{b} \tag{14.282}$$

with the use of Eq. (14.280). Substitution of Eq. (14.277) into Eq. (14.282) gives:

$$\theta_{C-H_{ethylene},H_2MO} = 45.50° \tag{14.283}$$

Then, the distance $d_{C-H_{ethylene},H_2MO}$ along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$d_{C-H_{ethylene},H_2MO} = a\cos\theta_{C-H_{ethylene},H_2MO} \tag{14.284}$$

Substitution of Eqs. (14.273) and (14.283) into Eq. (14.284) gives:

$$d_{C-H_{ethylene},H_2MO} = 1.10002a_0 = 5.82107\ X\ 10^{-11}\ m \tag{14.285}$$

The distance $d_{C-H_{ethylene}2sp^3HO}$ along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals is given by:

$$d_{C-H_{ethylene}2sp^3HO} = d_{C-H_{ethylene},H_2MO} - c' \tag{14.286}$$

Substitution of Eqs. (14.274) and (14.285) into Eq. (14.286) gives:

$$d_{C-H_{ethylene}2sp^3HO} = 0.07713a_0 = 4.08171\ X\ 10^{-12}\ m \tag{14.287}$$

BOND ANGLE OF THE CH_2 GROUPS

Each CH_2 MO comprises a linear combination of two $C-H$-bond MOs. Each $C-H$-bond MO comprises the superposition of a H_2-type ellipsoidal MO and the $C_{ethylene}2sp^3$ HO. A bond is also possible between the two H atoms of the $C-H$ bonds. Such $H-H$ bonding would decrease the $C-H$ bond strength since electron density would be shifted from the $C-H$ bonds to the $H-H$ bond. Thus, the bond angle between the two $C-H$ bonds is determined by the condition that the total energy of the H_2-type ellipsoidal MO between the terminal H atoms of the $C-H$ bonds is zero. From Eqs. (11.79) and (13.228), the distance from the origin to each focus of the $H-H$ ellipsoidal MO is:

$$c' = a\sqrt{\frac{\hbar^2 4\pi\varepsilon_0}{m_e e^2 2a}} = \sqrt{\frac{aa_0}{2}} \tag{14.288}$$

The internuclear distance from Eq. (13.229) is:

$$2c' = 2\sqrt{\frac{aa_0}{2}} \tag{14.289}$$

The length of the semiminor axis of the prolate spheroidal $H-H$ MO $b=c$ is given by Eq. (14.62).

The bond angle of the CH_2 groups of ethane is derived by using the orbital composition and an energy matching factor as in the case with the dihydrogen carbide radical and the CH_3 groups of ethane. Since the two H_2-type ellipsoidal MOs initially comprise 75% of the H electron density of H_2 and the energy of each H_2-type ellipsoidal MO is matched to that of the $C_{ethylene}2sp^3$ HO, the component energies and the total energy E_T of the $H-H$ bond are given by Eqs. (13.67-13.73) except that V_e, T, and V_m are corrected for the hybridization-energy-matching factor of 0.85252. Hybridization with 25% electron donation to the $C=C$-bond gives rise to the $C_{ethylene}2sp^3$ HO-shell Coulombic energy $E_{Coulomb}\left(C_{ethylene}, 2sp^3\right)$ given by Eq. (14.245). The corresponding normalization factor for determining the zero of the total $H-H$ bond energy is given by the ratio of $15.95955\ eV$, the magnitude of $E_{Coulomb}\left(C_{ethylene}, 2sp^3\right)$ given by Eq. (14.245), and $13.605804\ eV$, the magnitude of the Coulombic energy between the electron and proton of H given by Eq. (1.264). The hybridization energy factor $C_{ethyleneC2sp^3HO}$ is:

$$C_{ethyleneC2sp^3HO} = \frac{\frac{e^2}{8\pi\varepsilon_0 a_0}}{\frac{e^2}{8\pi\varepsilon_0 r_{ethylene2sp^3}}} = \frac{\frac{e^2}{8\pi\varepsilon_0 a_0}}{\frac{e^2}{8\pi\varepsilon_0 0.85252 a_0}} = \frac{13.605804\ eV}{15.95955\ eV} = 0.85252 \tag{14.290}$$

Substitution of Eq. (14.290) into Eq. (13.233) or Eq. (14.195) with the hybridization factor of 0.85252 gives:

$$0 = \left[\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2}}}\left[(0.85252)^{-1}\left(\frac{3}{2}-\frac{3}{8}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{2}}}{a-\sqrt{\frac{aa_0}{2}}}-1\right]\left[1+\sqrt{\frac{2\hbar\sqrt{\frac{0.75e^2}{4\pi\varepsilon_0 a^3}}}{m_e c^2}}\right]\right.$$
$$\left.+\hbar\sqrt{\frac{\frac{0.75e^2}{8\pi\varepsilon_0 a^3}-\frac{e^2}{8\pi\varepsilon_0\left(a+c'\right)^3}}{0.5m_p}}\right] \tag{14.291}$$

From the energy relationship given by Eq. (14.291) and the relationship between the axes given by Eqs. (14.192-14.193) and (14.62-14.63), the dimensions of the $H-H$ MO can be solved.

The most convenient way to solve Eq. (14.291) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a = 6.0400a_0 = 3.1962\ X\ 10^{-10}\ m \tag{14.292}$$

Substitution of Eq. (14.292) into Eq. (14.288) gives:

$$c' = 1.7378a_0 = 9.1961\ X\ 10^{-11}\ m \tag{14.293}$$

The internuclear distance given by multiplying Eq. (14.293) by two is:

$$2c' = 3.4756a_0 = 1.8392\ X\ 10^{-10}\ m \tag{14.294}$$

Substitution of Eqs. (14.292-14.293) into Eq. (14.62) gives:

$$b = c = 5.7846a_0 = 3.0611\ X\ 10^{-10}\ m \tag{14.295}$$

Substitution of Eqs. (14.292-14.293) into Eq. (14.63) gives:

$$e = 0.2877 \tag{14.296}$$

From, $2c'_{H-H}$ (Eq. (14.294)), the distance between the two H atoms when the total energy of the corresponding MO is zero (Eq. (14.291)), and $2c'_{C-H}$ (Eq. (14.275)), the internuclear distance of each $C-H$ bond, the corresponding bond angle can be determined from the law of cosines. Using, Eq. (13.242), the bond angle θ_{HCH} between the $C-H$ bonds is:

$$\theta_{HCH} = \cos^{-1}\left(\frac{2\left(2.04578\right)^2 - \left(3.4756\right)^2}{2\left(2.04578\right)^2}\right) = \cos^{-1}\left(-0.44318\right) = 116.31° \tag{14.297}$$

The experimental angle between the $C-H$ bonds is [11]:

$$\theta_{HCH} = 116.6° \tag{14.298}$$

The $C=C$ bond is along the z-axis. Thus, based on the symmetry of the equivalent bonds, the bond angle $\theta_{C=C-H}$ between the internuclear axis of the $C=C$ bond and a H atom of the CH_2 groups is given by:

$$\theta_{C=C-H} = \frac{\left(360° - \theta_{HCH}\right)}{2} \tag{14.299}$$

Substitution of Eq. (14.298) into Eq. (14.299) gives:

$$\theta_{C=C-H} = 121.85° \tag{14.300}$$

The experimental angle between the $C=C-H$ bonds is [11]:

$$\theta_{C=C-H} = 121.7° \tag{14.301}$$

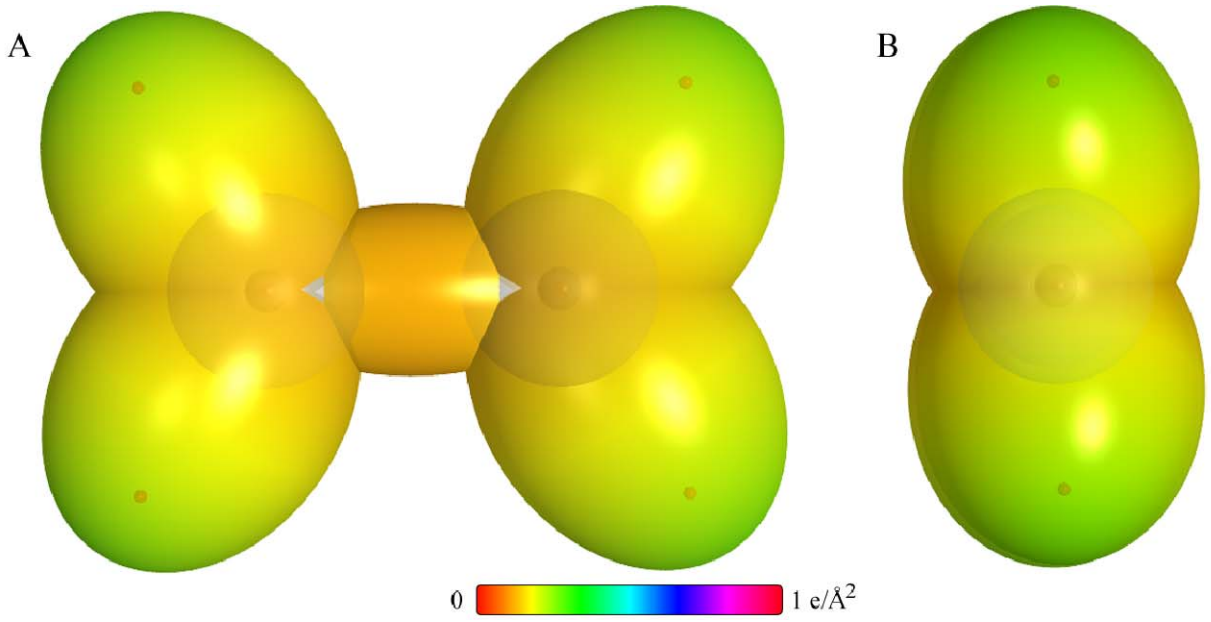
and [3]

$$\theta_{C=C-H} = 121.3° \tag{14.302}$$

The $C=C$ bond and H atoms of ethylene line in a plane, and rotation about the $C=C$ is not possible due to conservation of angular momentum in the two sets of spin-paired electrons of the double bond. The CH_2CH_2 MO shown in Figure 14.10 was rendered using these parameters.

The charge-density in the $C=C$-bond MO is increased by a factor of 0.25 per bond with the formation of the $C_{ethylene}2sp^3$ HOs each having a smaller radius. Using the orbital composition of the CH_2 groups (Eq. (14.269)) and the $C=C$-bond MO (Eq. (14.242)), the radii of $C1s = 0.17113a_0$ (Eq. (10.51)) and $C_{ethylene}2sp^3 = 0.85252a_0$ (Eq. (14.244)) shells, and the parameters of the $C=C$-bond (Eqs. (13.3-13.4), (14.254-14.256), and (14.258-14.268)), the parameters of the $C-H$-bond MOs (Eqs. (13.3-13.4), (14.273-14.275), and (14.277-14.287)), and the bond-angle parameters (Eqs. (14.297-14.302)), the charge-density of the CH_2CH_2 MO comprising the linear combination of two sets of two $C-H$-bond MOs and a $C=C$-bond MO bridging the two CH_2 groups is shown in Figure 14.10. Each $C-H$-bond MO comprises a H_2-type ellipsoidal MO and a $C_{ethylene}2sp^3$ HO having the dimensional diagram shown in Figure 14.9. The $C=C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{ethylene}2sp^3$ HOs having the dimensional diagram shown in Figure 14.8.

Figure 14.10. CH_2CH_2 MO comprising the linear combination of two sets of two $C-H$ -bond MOs and a $C=C$ -bond MO. (A) Color scale, translucent view of the charge-density of the $C=C$ -bond MO with the $C_{ethylene}2sp^3$ HOs shown transparently. The $C=C$ -bond MO comprises a H_2 -type ellipsoidal MO bridging two sets of two $C_{ethylene}2sp^3$ HOs. For each $C-H$ and the $C=C$ bond, the ellipsoidal surface of the H_2 -type ellipsoidal MO that transitions to the $C_{ethylene}2sp^3$ HO, the $C_{ethylene}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown. (B)-(D) End-on view, translucent view high-lighting the $C=C$ -bond MO, and opaque view of the charge-density of the CH_2CH_2 MO, respectively.



ENERGIES OF THE CH_2 GROUPS

The energies of each CH_2 group of ethylene are given by the substitution of the semiprincipal axes (Eqs. (14.273-14.274) and (14.277)) into the energy equations of dihydrogen carbide (Eqs. (13.510-13.514)), with the exception that two times $E_T\left(C=C,2sp^3\right)$ (Eq. (14.247)) is subtracted from $E_T\left(CH_2\right)$ in Eq. (13.514).

$$V_e = 2\left(0.91771\right)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -76.00757\ eV \tag{14.303}$$

$$V_p = \frac{2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 26.60266\ eV \tag{14.304}$$

$$T = 2\left(0.91771\right)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 24.21459\ eV \tag{14.305}$$

$$V_m = 2\left(0.91771\right)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -12.10730\ eV \tag{14.306}$$

$$E_{T_{ethylene}}\left(CH_2\right) = \left(\begin{array}{l} -\dfrac{2e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+c'}{a-c'}-1\right] \\ -14.63489\ eV-\left(-2.26758\ eV\right)\end{array}\right) = -49.66493\ eV \tag{14.307}$$

where $E_{T_{ethylene}}\left(CH_2\right)$ is given by Eq. (14.270) which is reiteratively matched to Eq. (13.496) within five-significant-figure round off error.

VIBRATION OF THE $^{12}CH_2$ GROUPS

The vibrational energy levels of CH_2 in ethylene may be solved as two equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

THE DOPPLER ENERGY TERMS OF THE $^{12}CH_2$ GROUPS

The equations of the radiation reaction force of the CH_2 groups in ethylene are the same as those of the dihydrogen carbide radical with the substitution of the CH_2-group parameters. Using Eq. (13.515), the angular frequency of the reentrant oscillation in the transition state is:

$$\omega = \sqrt{\frac{0.75e^2}{4\pi\varepsilon_0 b^3}} = 2.75685\ X\ 10^{16}\ rad/s \tag{14.308}$$

where b is given by Eq. (14.277). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)):

$$\bar{E}_K = \hbar\omega = \hbar 2.75685\ X\ 10^{16}\ rad/s = 18.14605\ eV \tag{14.309}$$

In Eq. (11.181), substitution of $E_T\left(H_2\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each H_2-type MO, for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.309) for $\bar{E}_K$ gives the Doppler energy of the electrons of each of the two bonds for the reentrant orbit:

$$\bar{E}_D \cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}} = -31.63537\ eV\sqrt{\frac{2e(18.14605\ eV)}{m_e c^2}} = -0.26660\ eV \tag{14.310}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of CH_2 due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (14.310) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of each $C-H$ bond. Using ω_e given by Eq. (13.458) for $\bar{E}_{Kvib}$ of the transition state having two independent bonds, $\bar{E}'_{ethylene\ osc}\left(^{12}CH_2\right)$ per bond is:

$$\bar{E}'_{ethylene\ osc}\left(^{12}CH_2\right) = \bar{E}_D + \bar{E}_{Kvib} = \bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{14.311}$$

$$\bar{E}'_{ethylene\ osc}\left(^{12}CH_2\right) = -0.26660\ eV + \frac{1}{2}(0.35532\ eV) = -0.08894\ eV \tag{14.312}$$

Given that the vibration and reentrant oscillation is for two $C-H$ bonds, $\bar{E}_{ethylene\ osc}\left(^{12}CH_2\right)$, is:

$$\bar{E}_{ethylene\ osc}\left(^{12}CH_2\right) = 2\left(\bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) = 2\left(-0.26660\ eV + \frac{1}{2}(0.35532\ eV)\right) = -0.17788\ eV \tag{14.313}$$

TOTAL AND DIFFERENCE ENERGIES OF THE $^{12}CH_2$ GROUPS

$E_{ethyleneT+osc}\left(^{12}CH_2\right)$, the total energy of each $^{12}CH_2$ group including the Doppler term, is given by the sum of $E_{T_{ethylene}}\left(CH_2\right)$ (Eq. (14.307)) and $\bar{E}_{ethylene\ osc}\left(^{12}CH_2\right)$ given by Eq. (14.313):

$$\begin{aligned} E_{ethyleneT+osc}\left(^{12}CH_2\right) &= \begin{pmatrix} V_e + T + V_m + V_p + E\left(C, 2sp^3\right) \\ -2E_T\left(C=C, 2sp^3\right) + \bar{E}_{ethylene\ osc}\left(^{12}CH_2\right) \end{pmatrix} \\ &= E_{T_{ethylene}}\left(CH_2\right) + \bar{E}_{ethylene\ osc}\left(^{12}CH_2\right) \end{aligned} \tag{14.314}$$

$$E_{ethyleneT+osc}\left({}^{12}CH_2\right)=\left\{\begin{array}{l}\left(\begin{array}{l}\dfrac{-2e^2}{8\pi\varepsilon_0 c'}\left[(0.91771)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+c'}{a-c'}-1\right]\\ -14.63489\ eV-(-2.26759\ eV)\end{array}\right)\\ -2\left((31.63536831\ eV)\sqrt{\dfrac{2\hbar\sqrt{\dfrac{3}{4}\dfrac{e^2}{4\pi\varepsilon_0 b^3}}}{m_e c^2}}-\dfrac{1}{2}\hbar\sqrt{\dfrac{k}{\mu}}\right)\end{array}\right\}$$
$$=-49.66493\ eV-2\left(0.26660\ eV-\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \tag{14.315}$$

From Eqs. (14.313-14.315), the total energy of each ${}^{12}CH_2$ is:

$$\begin{aligned}E_{ethyleneT+osc}\left({}^{12}CH_2\right)&=-49.66493\ eV+\bar{E}_{ethylene\ osc}\left({}^{12}CH_2\right)\\&=-49.66493\ eV-2\left(0.26660\ eV-\frac{1}{2}(0.35532\ eV)\right)\\&=-49.84282\ eV\end{aligned} \tag{14.316}$$

where ω_e given by Eq. (13.458) was used for the $\hbar\sqrt{\dfrac{k}{\mu}}$ term.

The total energy for each dihydrogen carbide radical given by Eq. (13.523) is:

$$\begin{aligned}E_{radicalT+osc}\left({}^{12}CH_2\right)&=-49.66493\ eV+\bar{E}_{radicalosc}\left({}^{12}CH_2\right)\\&=-49.66493\ eV-2\left(0.25493\ eV-\frac{1}{2}(0.35532\ eV)\right)\\&=-49.81948\ eV\end{aligned} \tag{14.317}$$

The difference in energy between the CH_2 groups and the dihydrogen carbide radical $\Delta E_{T+osc}\left({}^{12}CH_2\right)$ is given by two times the difference between Eqs. (14.316) and (14.317):

$$\begin{aligned}\Delta E_{T+osc}\left({}^{12}CH_2\right)&=2\left(E_{ethyleneT+osc}\left({}^{12}CH_2\right)-E_{radicalT+osc}\left({}^{12}CH_2\right)\right)\\&=2\left(-49.84282\ eV-(-49.81948\ eV)\right)\\&=-0.04667\ eV\end{aligned} \tag{14.318}$$

SUM OF THE ENERGIES OF THE $C=C$ σ MO AND THE HOS OF ETHYLENE

The energy components of V_e, V_p, T, V_m, and E_T of the $C=C$-bond MO are the same as those of the CH MO except that each term is multiplied by two corresponding to the double bond and the energy term corresponding to the $C_{ethylene}2sp^3$ HOs in the equation for E_T is zero. The energies of each $C=C$-bond MO are given by the substitution of the semiprincipal axes (Eqs. (14.254-14.255) and (14.258)) into two times the energy equations of the CH MO (Eqs. (13.449-13.453)), with the exception that zero replaces $E\left(C,2sp^3\right)$ in Eq. (13.453).

$$V_e=2(0.91771)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=-102.08992\ eV \tag{14.319}$$

$$V_p=2\frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}=21.48386\ eV \tag{14.320}$$

$$T=2(0.91771)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=34.67062\ eV \tag{14.321}$$

$$V_m=2(0.91771)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=-17.33531\ eV \tag{14.322}$$

$$E_T(C=C,\sigma)=-\frac{2e^2}{8\pi\varepsilon_0 c'}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]=-63.27075\ eV \tag{14.323}$$

where $E_T\left(C=C,\sigma\right)$ is the total energy of the $C=C$ σ MO given by Eq. (14.251) which is reiteratively matched to two times Eq. (13.75) within five-significant-figure round off error.

The total energy of the $C=C$-bond MO, $E_T\left(C=C\right)$, is given by the sum of two times $E_T\left(C=C,2sp^3\right)$, the energy change of each $C2sp^3$ shell due to the decrease in radius with the formation of the $C=C$-bond MO (Eq. (14.247)), and $E_T\left(C=C,\sigma\right)$, the σ MO contribution given by Eq. (14.252).

$$\begin{aligned} E_T\left(C=C\right) &= 2E_T\left(C=C,2sp^3\right)+E_T\left(C=C,\sigma\right) \\ &= \left(\begin{array}{l} 2\left(-1.13380\ eV\right)+ \\ \left(-\frac{2e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]\right) \end{array}\right) \\ &= 2\left(-1.13380\ eV\right)+\left(-63.27074\ eV\right) \\ &= -65.53833\ eV \end{aligned} \tag{14.324}$$

VIBRATION OF ETHYLENE

The vibrational energy levels of CH_2CH_2 may be solved as two sets of two equivalent coupled harmonic oscillators with a bridging harmonic oscillator by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

THE DOPPLER ENERGY TERMS OF THE $C=C$-BOND MO OF ETHYLENE

The equations of the radiation reaction force of the $C=C$-bond MO are given by Eq. (13.142), except the force-constant factor is $\left(0.93172\right)0.5$ based on the force constant k' of Eq. (14.248), and the $C=C$-bond MO parameters are used. The angular frequency of the reentrant oscillation in the transition state is:

$$\omega=\sqrt{\frac{0.91771\frac{\left(0.5\right)e^2}{4\pi\varepsilon_0 b^3}}{m_e}}=4.30680\ X\ 10^{16}\ rad/s \tag{14.325}$$

where b is given by Eq. (14.258). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K=\hbar\omega=\hbar 4.30680\ X\ 10^{16}\ rad/s=28.34813\ eV \tag{14.326}$$

In Eq. (11.181), substitution of $E_T\left(C=C\right)/2$ (Eq. (14.324)) for E_{hv}, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.326) for $\bar{E}_K$ gives the Doppler energy of the electrons of each of the two bonds for the reentrant orbit:

$$\bar{E}_D\cong E_{hv}\sqrt{\frac{2\bar{E}_K}{Mc^2}}=-32.76916\ eV\sqrt{\frac{2e\left(28.34813\ eV\right)}{m_e c^2}}=-0.34517\ eV \tag{14.327}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $C=C$-bond MO due to the reentrant orbit of the bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (14.327) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of the $C=C$ bond. Using the experimental $C=C$ $E_{vib}\left(\upsilon_3\right)$ of 1443.5 cm^{-1} $\left(0.17897\ eV\right)$ [12] for $\bar{E}_{Kvib}$ of the transition state having two bonds, $\bar{E}'_{osc}\left(C=C,\sigma\right)$ per bond is:

$$\bar{E}'_{osc}\left(C=C,\sigma\right)=\bar{E}_D+\bar{E}_{Kvib}=\bar{E}_D+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{14.328}$$

$$\bar{E}'_{osc}\left(C=C,\sigma\right)=-0.34517\ eV+\frac{1}{2}\left(0.17897\ eV\right)=-0.25568\ eV \tag{14.329}$$

Given that the vibration and reentrant oscillation is for two $C-C$ bonds of the $C=C$ double bond, $\bar{E}_{ethylene\ osc}\left(C=C,\sigma\right)$, is:

$$\bar{E}_{ethylene\ osc}\left(C=C,\sigma\right)=2\left(\bar{E}_D+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)=2\left(-0.34517\ eV+\frac{1}{2}\left(0.17897\ eV\right)\right)=-0.51136\ eV \tag{14.330}$$

TOTAL ENERGIES OF THE $C=C$-BOND MO OF ETHYLENE

$E_{T+osc}\left(C=C\right)$, the total energy of the $C=C$-bond MO including the Doppler term, is given by the sum of $E_T\left(C=C\right)$ (Eq. (14.324)) and $\overline{E}_{ethylene\ osc}\left(C=C,\sigma\right)$ given by Eq. (14.330).

$$\begin{aligned}E_{T+osc}\left(C=C\right)&=V_e+T+V_m+V_p+2E_T\left(C=C,2sp^3\right)+\overline{E}_{ethylene\ osc}\left(C=C,\sigma\right)\\&=E_T\left(C=C,\sigma\right)+2E_T\left(C=C,2sp^3\right)+\overline{E}_{ethylene\ osc}\left(C=C,\sigma\right)\\&=E_T\left(C=C\right)+\overline{E}_{ethylene\ osc}\left(C=C,\sigma\right)\end{aligned}\tag{14.331}$$

$$\begin{aligned}E_{T+osc}\left(C=C\right)&=\left\{\begin{pmatrix}\dfrac{-2e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+c'}{a-c'}-1\right]+2E_T\left(C=C,2sp^3\right)\\ \\1+\left(2\right)\left(\dfrac{1}{2}\right)\sqrt{\dfrac{2\hbar\sqrt{\dfrac{\left(0.91771\right)\dfrac{1}{2}\dfrac{e^2}{4\pi\varepsilon_0 b^3}}{m_e}}}{m_e c^2}}\end{pmatrix}+2\left(\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)\right\}\\&=-65.53833\ eV-2\left(0.34517\ eV-\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)\end{aligned}\tag{14.332}$$

From Eqs. (14.330-14.332), the total energy of the $C=C$-bond MO is:

$$\begin{aligned}E_{T+osc}\left(C=C\right)&=-63.27074\ eV+2E_T\left(C=C,2sp^3\right)+\overline{E}_{ethylene\ osc}\left(C=C,\sigma\right)\\&=-63.27074\ eV+2\left(-1.13380\ eV\right)-2\left(0.34517\ eV-\frac{1}{2}\left(0.17897\ eV\right)\right)\\&=-66.04969\ eV\end{aligned}\tag{14.333}$$

where the experimental E_{vib} was used for the $\hbar\sqrt{\dfrac{k}{\mu}}$ term.

BOND ENERGY OF THE $C=C$ BOND OF ETHYLENE

The dissociation energy of the $C=C$ bond of CH_2CH_2, $E_D\left(H_2C=CH_2\right)$, is given by four times $E\left(C,2sp^3\right)$ (Eq. (14.146)), the initial energy of each $C2sp^3$ HO of each CH_2 radical that forms the double $C=C$ bond, minus the sum of $\Delta E_{T+osc}\left(^{12}CH_2\right)$ (Eq. (14.318)), the energy change going from the dihydrogen carbide radicals to the CH_2 groups of ethylene, and $E_{T+osc}\left(C=C\right)$ (Eq. (14.333)). Thus, the dissociation energy of the $C=C$ bond of CH_2CH_2, is:

$$\begin{aligned}E_D\left(H_2C=CH_2\right)&=4\left(E\left(C,2sp^3\right)\right)-\left(\Delta E_{T+osc}\left(^{12}CH_2\right)+E_{T+osc}\left(C=C\right)\right)\\&=4\left(-14.63489\ eV\right)-\left(-0.04667\ eV-66.04969\ eV\right)\\&=4\left(-14.63489\ eV\right)-\left(-66.09636\ eV\right)\\&=7.55681\ eV\end{aligned}\tag{14.334}$$

The experimental dissociation energy of the $C=C$ bond of CH_2CH_2 is [7]:

$$E_D\left(H_2C-CH_2\right)=7.5969\ eV\tag{14.335}$$

The results of the determination of bond parameters of CH_2CH_2 are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

ACETYLENE MOLECULE ($CHCH$)

The acetylene molecule $CHCH$ is formed by the reaction of two hydrogen carbide radicals:

$$CH + CH \rightarrow CHCH \tag{14.336}$$

$CHCH$ can be solved using the same principles as those used to solve the methane series $CH_{n=1,2,3,4}$ as well as ethane, wherein the $2s$ and $2p$ shells of each C hybridize to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. First, two sets of one H atomic orbital (AO) combine with two sets of one carbon $2sp^3$ HO to form two hydrogen carbide groups comprising a linear combination of two diatomic H_2-type MOs developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section. Then, the two CH groups bond by forming a H_2-type MO between the remaining three $C2sp^3$ HOs on each carbon atom.

FORCE BALANCE OF THE $C \equiv C$-BOND MO OF ACETYLENE

$CHCH$ comprises a chemical bond between two CH radicals wherein each radical comprises a chemical bond between a carbon and a hydrogen atom. The solution of the parameters of CH is given in the Hydrogen Carbide (CH) section. The $C-H$ bond of CH having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of 75% H_2-type ellipsoidal MO and 25% $C2sp^3$ HO. The proton of the H atom and the nucleus of the C atom are along each internuclear axis and serve as the foci. As in the case of H_2, the $C-H$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $C2sp^3$ HO for distances shorter than the radius of the $C2sp^3$ shell since it is energetically unfavorable. Thus, the MO surface comprises a prolate spheroid at the H proton that is continuous with the $C2sp^3$ shell at the C atom whose nucleus serves as the other focus. The electron configuration and the energy, $E\left(C,2sp^3\right)$, of the $C2sp^3$ shell is given by Eqs. (13.422) and (13.428), respectively. The central paramagnetic force due to spin of the $C-H$ bond is provided by the spin-pairing force of the CH MO that has the symmetry of an s orbital that superimposes with the $C2sp^3$ orbitals such that the corresponding angular momenta are unchanged.

Two CH radicals bond to form $CHCH$ by forming a MO between the two pairs of three remaining $C2sp^3$-HO electrons of the two carbon atoms. However, in this case, the sharing of electrons between two $C2sp^3$ HOs to form a MO comprising six spin-paired electrons permits each $C2sp^3$ HO to decrease in radius and energy.

As in the case of the $C-H$ bonds, the $C \equiv C$-bond MO is a prolate-spheroidal-MO surface that cannot extend into $C2sp^3$ HO for distances shorter than the radius of the $C2sp^3$ shell of each atom. Thus, the MO surface comprises a partial prolate spheroid in between the carbon nuclei and is continuous with the $C2sp^3$ shell at each C atom. The energy of the H_2-type ellipsoidal MO is matched to that of the $C2sp^3$ shell. As in the case of previous examples of energy-matched MOs such as those of OH, NH, CH, the $C=O$-bond MO of CO_2, the $C-C$-bond MO of CH_3CH_3, and the $C=C$-bond MO of CH_2CH_2, the $C \equiv C$-bond MO of acetylene must comprise 75% of a H_2-type ellipsoidal MO in order to match potential, kinetic, and orbital energy relationships. Thus, the $C \equiv C$-bond MO must comprise a linear combination of three MOs wherein each comprises two $C2sp^3$ HOs and 75% of a H_2-type ellipsoidal MO divided between the $C2sp^3$ HOs:

$$3\left(2C2sp^3 + 0.75\ H_2\ MO\right) \rightarrow C \equiv C - bond\ MO \tag{14.337}$$

The linear combination of each H_2-type ellipsoidal MO with each $C2sp^3$ HO further comprises an excess 25% charge-density contribution from each $C2sp^3$ HO to the $C \equiv C$-bond MO to achieve an energy minimum. The force balance of the $C \equiv C$-bond MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.337) and the energy matching condition between the $C2sp^3$-HO components of the MO.

Similarly, the energies of each CH MO involve each $C2sp^3$ and each $H1s$ electron with the formation of each $C-H$ bond. The sum of the energies of the H_2-type ellipsoidal MOs is matched to that of the $C2sp^3$ shell. This energy is determined by the considering the effect of the donation of 25% electron density from the three pairs of $C2sp^3$ HOs to the $C \equiv C$-bond MO with the formation of the $C_{acetylene}2sp^3$ HOs each having a smaller radius. The $2sp^3$ hybridized orbital arrangement is given by Eq. (14.140). The sum $E_T\left(C,2sp^3\right)$ of calculated energies of C, C^+, C^{2+}, and C^{3+} is given by Eq. (14.141). The radius r_{2sp^3} of the $C2sp^3$ shell is given by Eq. (14.142). The Coulombic energy $E_{Coulomb}\left(C,2sp^3\right)$ and the energy $E\left(C,2sp^3\right)$ of the outer electron of the $C2sp^3$ shell are given by Eqs. (14.143) and (14.146), respectively.

Next, consider the formation of the $C \equiv C$-bond MO of acetylene from two CH radicals, each having a $C2sp^3$ electron with an energy given by Eq. (14.146). The total energy of the state is given by the sum over the four electrons. The sum $E_T\left(C_{acetylene}, 2sp^3\right)$ of calculated energies of $C2sp^3$, C^+, C^{2+}, and C^{3+} from Eqs. (10.123), (10.113-10.114), (10.68), and (10.48), respectively, is

$$\begin{aligned} E_T\left(C_{acetylene}, 2sp^3\right) &= -\left(64.3921\ eV + 48.3125\ eV + 24.2762\ eV + E\left(C, 2sp^3\right)\right) \\ &= -\left(64.3921\ eV + 48.3125\ eV + 24.2762\ eV + 14.63489\ eV\right) \\ &= -151.61569\ eV \end{aligned} \tag{14.338}$$

where $E\left(C, 2sp^3\right)$ (Eq. (14.146)) is the sum of the energy of C, $-11.27671\ eV$, and the hybridization energy. The orbital-angular-momentum interactions also cancel such that the energy of the $E_T\left(C_{acetylene}, 2sp^3\right)$ is purely Coulombic.

The sharing of electrons between three pairs of $C2sp^3$ HOs to form a $C \equiv C$-bond MO permits each participating hybridized orbital to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each participating $C2sp^3$ HO donates an excess of 25% of its electron density to the $C \equiv C$-bond MO to form an energy minimum. By considering this electron redistribution in the acetylene molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{acetylene\,2sp^3}$ of the $C2sp^3$ shell of acetylene may be calculated from the Coulombic energy using Eq. (10.102).

$$r_{acetylene\,2sp^3} = \left(\sum_{n=2}^{5}(Z-n) - 0.75\right)\frac{e^2}{8\pi\varepsilon_0\left(e151.61569\ eV\right)} = \frac{9.25e^2}{8\pi\varepsilon_0\left(e151.61569\ eV\right)} = 0.83008a_0 \tag{14.339}$$

where $Z = 6$ for carbon. Using Eqs. (10.102) and (14.339), the Coulombic energy $E_{Coulomb}\left(C_{acetylene}, 2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is:

$$E_{Coulomb}\left(C_{acetylene}, 2sp^3\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{acetylene\,2sp^3}} = \frac{-e^2}{8\pi\varepsilon_0 0.83008a_0} = -16.39089\ eV \tag{14.340}$$

During hybridization, the spin-paired $2s$ electrons are promoted to the $C2sp^3$ shell as unpaired electrons. The energy for the promotion is the magnetic energy given by Eq. (13.152). Using Eqs. (14.145) and (14.340), the energy $E\left(C_{acetylene}, 2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is

$$E\left(C_{acetylene}, 2sp^3\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{acetylene\,2sp^3}} + \frac{2\pi\mu_0 e^2\hbar^2}{m_e^2\left(r_3\right)^3} = -16.39089\ eV + 0.19086\ eV = -16.20002\ eV \tag{14.341}$$

Thus, $E_T\left(C \equiv C, 2sp^3\right)$, the energy change of each $C2sp^3$ shell with the formation of the $C \equiv C$-bond MO is given by the difference between Eq. (14.146) and Eq. (14.341):

$$E_T\left(C \equiv C, 2sp^3\right) = E\left(C_{acetylene}, 2sp^3\right) - E\left(C, 2sp^3\right) = -16.20002\ eV - \left(-14.63489\ eV\right) = -1.56513\ eV \tag{14.342}$$

As in the case of Cl_2, each H_2-type ellipsoidal MO comprises 75% of the $C \equiv C$-bond MO shared between two $C2sp^3$ HOs corresponding to the electron charge density in Eq. (11.65) of $\frac{-0.75e}{2}$. But, the additional 25% charge-density contribution to each bond of the $C \equiv C$-bond MO causes the electron charge density in Eq. (11.65) to be $\frac{-e}{2} = -0.5e$. The corresponding force constant k' to determine the ellipsoidal parameter c' in terms of the central force of the foci (Eq. (11.65)) is given by Eq. (14.152). The distance from the origin to each focus c' is given by Eq. (14.153). The internuclear distance is given by Eq. (14.154). The length of the semiminor axis of the prolate spheroidal $C \equiv C$-bond MO $b = c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of the $C \equiv C$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the $C \equiv C$-bond MO are solved.

The general equations for the energy components of V_e, V_p, T, V_m, and E_T of the $C \equiv C$-bond MO are the same as those of the CH MO except that energy of the $C_{acetylene}2sp^3$ HO is used and the triple-bond nature is considered. In the case of a single bond, the prolate spheroidal H_2-type MO transitions to the $C_{acetylene}2sp^3$ HO of each carbon, and the energy of the $C_{acetylene}2sp^3$ shell must remain constant and equal to the $E\left(C_{acetylene}, 2sp^3\right)$ given by Eq. (14.391). Thus, the energy $E\left(C_{acetylene}, 2sp^3\right)$ in Eq. (14.391) adds to that of the energies of the corresponding H_2-type ellipsoidal MO. The second and third bonds of the triple $C \equiv C$-bond MO also transition to each $C_{acetylene}2sp^3$ HO of each C. The energy of a second and a third

H_2-type ellipsoidal MO adds to the first energy component, and the three bonds achieve an energy minimum as a linear combination of the three H_2-type ellipsoidal MOs each having the carbon nuclei as the foci. Each $C-C$-bond MO comprises the same $C_{acetylene}2sp^3$ HO shells of constant energy given by Eq. (14.391). As in the case of the water, NH_2, ammonia, and ethylene molecules given by Eqs. (13.180), (13.320), (13.372), and (14.251), respectively, the energy of the redundant shell is subtracted from the total energy of the linear combination of the σ MO. Thus, the total energy $E_T\left(C\equiv C,\sigma\right)$ of the σ component of the $C\equiv C$-bond MO is given by the sum of the energies of the three bonds each comprising the linear combination of the $C_{acetylene}2sp^3$ HO and the H_2-type ellipsoidal MO as given by Eq. (14.337) wherein the E_T terms add positively and the $E\left(C_{acetylene},2sp^3\right)$ term is positive due to the sum over a negative and two positive terms. Using Eqs. (13.431) and (14.341), $E_T\left(C\equiv C,\sigma\right)$ is given by:

$$\begin{aligned}E_T\left(C\equiv C,\sigma\right)&=E_T+E\left(C_{acetylene},2sp^3\right)-E\left(C_{acetylene},2sp^3\right)-E\left(C_{acetylene},2sp^3\right)\\&=-\frac{3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-E\left(C_{acetylene},2sp^3\right)\\&=-\frac{3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]+16.20002\ eV\end{aligned}\tag{14.343}$$

The total energy term of the triple $C\equiv C$-bond MO is given by the sum of the three H_2-type ellipsoidal MOs given by Eq. (11.212). To match this boundary condition, $E_T\left(C\equiv C,\sigma\right)$ given by Eq. (14.343) is set equal to three times Eq. (13.75):

$$E_T\left(C\equiv C,\sigma\right)=-\frac{3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]+16.20002\ eV=-94.90610\ eV\tag{14.344}$$

From the energy relationship given by Eq. (14.344) and the relationship between the axes given by Eqs. (14.153-14.154) and (13.62-13.63), the dimensions of the $C\equiv C$-bond MO can be solved.

Substitution of Eq. (14.153) into Eq. (14.344) gives:

$$\frac{3e^2}{8\pi\varepsilon_0\sqrt{aa_0}}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{aa_0}}{a-\sqrt{aa_0}}-1\right]=e111.10613\tag{14.345}$$

The most convenient way to solve Eq. (14.345) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is

$$a=1.28714a_0=6.81122\ X\ 10^{-11}\ m\tag{14.346}$$

Substitution of Eq. (14.346) into Eq. (14.153) gives:

$$c'=1.13452a_0=6.00362\ X\ 10^{-11}\ m\tag{14.347}$$

The internuclear distance given by multiplying Eq. (14.347) by two is:

$$2c'=2.26904a_0=1.20072\ X\ 10^{-10}\ m\tag{14.348}$$

The experimental bond distance is [3]:

$$2c'=1.203\ X\ 10^{-10}\ m\tag{14.349}$$

Substitution of Eqs. (14.346-14.347) into Eq. (13.62) gives:

$$b=c=0.60793a_0=3.21704\ X\ 10^{-11}\ m\tag{14.350}$$

Substitution of Eqs. (14.346-14.347) into Eq. (13.63) gives:

$$e=0.88143\tag{14.351}$$

The nucleus of the C atoms comprise the foci of the H_2-type ellipsoidal MO. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $C_{acetylene}2sp^3$ HO are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where $r_n=r_{acetylene2sp^3}=0.83008a_0$ is the radius of the $C_{acetylene}2sp^3$ shell. Substitution of Eqs. (14.346-14.347) into Eq. (13.261) gives:

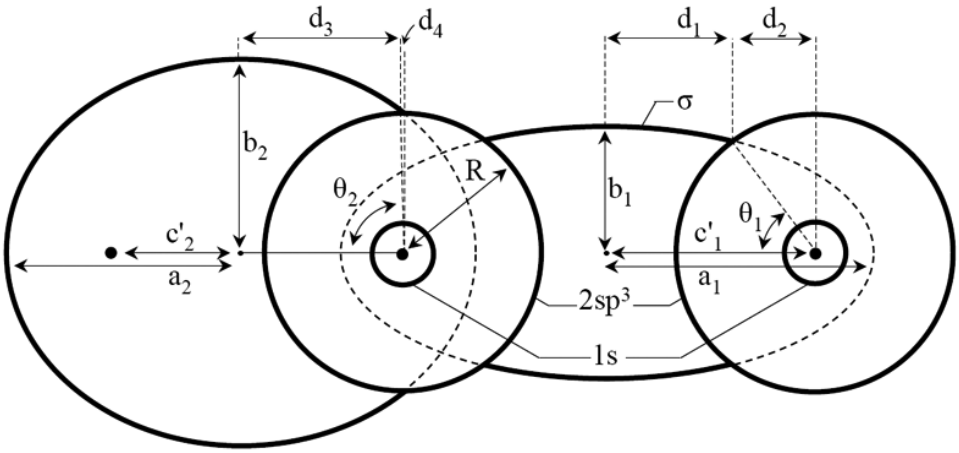
$$\theta'=137.91°\tag{14.352}$$

Then, the angle $\theta_{C\equiv C_{acetylene}2sp^3HO}$ the radial vector of the $C2sp^3$ HO makes with the internuclear axis is:

$$\theta_{C\equiv C_{acetylene}2sp^3HO}=180°-137.91°=42.09°\tag{14.353}$$

as shown in Figure 14.11.

Figure 14.11. The cross section of the $C \equiv C$-bond MO (σ MO) and one $C-H$-bond MO of acetylene showing the axes, angles, and point of intersection of each H_2-type ellipsoidal MO with the corresponding $C_{acetylene}2sp^3$ HO. The continuation of each H_2-type-ellipsoidal-MO basis element of the $C \equiv C$ bond and the $C-H$-bond beyond the intersection point with each $C_{acetylene}2sp^3$ shell and σ MO is shown as dashed since each only serves to solve the energy match with the $C_{acetylene}2sp^3$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of each intersection point. The actual charge density is shown by the solid lines. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, $d_1 : d_{C\equiv C_{acetylene},H_2MO}$, $\theta_1 : \theta_{C\equiv C_{acetylene}2sp^3HO}$, $d_2 : d_{C\equiv C_{acetylene}2sp^3HO}$, $R : r_{acetylene2sp^3}$, $\theta_2 : \theta_{C-H_{acetylene}2sp^3HO}$, $d_3 : d_{C-H_{acetylene},H_2MO}$, and $d_4 : d_{C-H_{acetylene}2sp^3HO}$.



Consider the right-hand intersection point. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{C\equiv C_{acetylene},H_2MO}$ satisfies the following relationship:

$$r_{acetylene2sp^3} \sin\theta_{C\equiv C_{acetylene}2sp^3HO} = 0.83008a_0 \sin\theta_{C\equiv C_{acetylene}2sp^3HO} = b\sin\theta_{C\equiv C_{acetylene},H_2MO} \tag{14.354}$$

such that

$$\theta_{C\equiv C_{acetylene},H_2MO} = \sin^{-1}\frac{0.83008a_0 \sin\theta_{C\equiv C_{acetylene}2sp^3HO}}{b} = \sin^{-1}\frac{0.83008a_0 \sin 42.09°}{b} \tag{14.355}$$

with the use of Eq. (14.353). Substitution of Eq. (14.350) into Eq. (14.355) gives:

$$\theta_{C\equiv C_{acetylene},H_2MO} = 66.24° \tag{14.356}$$

Then, the distance $d_{C\equiv C_{acetylene},H_2MO}$ along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$d_{C\equiv C_{acetylene},H_2MO} = a\cos\theta_{C\equiv C_{acetylene},H_2MO} \tag{14.357}$$

Substitution of Eqs. (14.346) and (14.356) into Eq. (14.357) gives:

$$d_{C\equiv C_{acetylene},H_2MO} = 0.51853a_0 = 2.74396\ X\ 10^{-11}\ m \tag{14.358}$$

The distance $d_{C\equiv C_{acetylene}2sp^3HO}$ along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals is given by:

$$d_{C\equiv C_{acetylene}2sp^3HO} = c' - d_{C\equiv C_{acetylene},H_2MO} \tag{14.359}$$

Substitution of Eqs. (14.347) and (14.358) into Eq. (14.359) gives:

$$d_{C\equiv C_{acetylene}2sp^3HO} = 0.61599a_0 = 3.25966\ X\ 10^{-11}\ m \tag{14.360}$$

FORCE BALANCE OF THE CH MOS OF ACETYLENE

The $C-H$ bond of each of the two equivalent CH MOs must comprise 75% of a H_2-type ellipsoidal MO and a $C2sp^3$ HO as given by Eq. (13.429):

$$1\,C2sp^3 + 0.75\,H_2\ MO \rightarrow CH\ MO \tag{14.361}$$

The force balance of the CH MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (13.429) and the energy matching condition between the hydrogen and $C2sp^3$ HO components of the MO.

The force constant k' to determine the ellipsoidal parameter c' of the each H_2-type-ellipsoidal-MO component of the CH MO in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus c' is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $C-H$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the CH MO are solved.

Consider the formation of the triple $C\equiv C$-bond MO of acetylene from two CH radicals, each having a $C2sp^3$ shell with an energy given by Eq. (14.146). The energy components of V_e, V_p, T, V_m, and E_T are the same as those of the hydrogen carbide radical, except that two times $E_T\left(C\equiv C,2sp^3\right)$ is subtracted from $E_T\left(CH\right)$ of Eq. (13.495). The subtraction of the energy change of the $C2sp^3$ shells with the formation of the $C\equiv C$-bond MO matches the energy of the $C-H$-bond MOs to the decrease in the energy of the $C2sp^3$ HOs. Using Eqs. (13.495) and (14.342), $E_{T_{acetylene}}\left(CH\right)$ is given by:

$$E_{T_{acetylene}}\left(CH\right)=E_T+E\left(C,2sp^3\right)-2E_T\left(C\equiv C,2sp^3\right)=\begin{pmatrix}-\dfrac{e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+c'}{a-c'}-1\right]\\ -14.63489\ eV-\left(-3.13026\ eV\right)\end{pmatrix} \tag{14.362}$$

$E_{T_{acetylene}}\left(CH\right)$ given by Eq. (14.362) is set equal to the energy of the H_2-type ellipsoidal MO given by Eq. (13.75).

$$E_{T_{acetylene}}\left(CH\right)=\begin{pmatrix}-\dfrac{e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+c'}{a-c'}-1\right]\\ -14.63489\ eV-\left(-3.13026\ eV\right)\end{pmatrix}=-31.63537\ eV \tag{14.363}$$

From the energy relationship given by Eq. (14.363) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the CH MO can be solved.

Substitution of Eq. (13.60) into Eq. (14.363) gives:

$$\frac{e^2}{8\pi\varepsilon_0\sqrt{\dfrac{2aa_0}{3}}}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\dfrac{2aa_0}{3}}}{a-\sqrt{\dfrac{2aa_0}{3}}}-1\right]=e20.13074 \tag{14.364}$$

The most convenient way to solve Eq. (14.364) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is

$$a=1.48719a_0=7.86987\ X\ 10^{-11}\ m \tag{14.365}$$

Substitution of Eq. (14.365) into Eq. (14.60) gives:

$$c'=0.99572a_0=5.26913\ X\ 10^{-11}\ m \tag{14.366}$$

The internuclear distance given by multiplying Eq. (14.366) by two is:

$$2c'=1.99144a_0=1.05383\ X\ 10^{-10}\ m \tag{14.367}$$

The experimental bond distance is [3]:

$$2c'=1.060\ X\ 10^{-10}\ m \tag{14.368}$$

Substitution of Eqs. (14.365-14.366) into Eq. (14.62) gives:

$$b=c=1.10466a_0=5.84561\ X\ 10^{-11}\ m \tag{14.369}$$

Substitution of Eqs. (14.365-14.366) into Eq. (14.63) gives:

$$e=0.66953 \tag{14.370}$$

The nucleus of the H atom and the nucleus of the C atom comprise the foci of each H_2-type ellipsoidal MO. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $C_{acetylene}2sp^3$ HO are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where $r_n=r_{acetylene\,2sp^3}=0.83008a_0$ is the radius of the $C_{acetylene}2sp^3$ shell. Substitution of Eqs. (14.365-14.366) into Eq. (13.261) gives:

$$\theta'=90.99^\circ \tag{14.371}$$

Then, the angle $\theta_{C-H_{acetylene}2sp^3HO}$ the radial vector of the $C2sp^3$ HO makes with the internuclear axis is

$$\theta_{C-H_{acetylene}2sp^3HO} = 180° - 90.99° = 89.01° \tag{14.372}$$

as shown in Figure 14.11. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{C-H_{acetylene},H_2MO}$ satisfies the following relationship:

$$r_{acetylene2sp^3} \sin\theta_{C-H_{acetylene}2sp^3HO} = 0.83008a_0 \sin\theta_{C-H_{acetylene}2sp^3HO} = b\sin\theta_{C-H_{acetylene},H_2MO} \tag{14.373}$$

such that

$$\theta_{C-H_{acetylene},H_2MO} = \sin^{-1}\frac{0.83008a_0 \sin\theta_{C-H_{acetylene}2sp^3HO}}{b} = \sin^{-1}\frac{0.83008a_0 \sin 89.01°}{b} \tag{14.374}$$

with the use of Eq. (14.372). Substitution of Eq. (14.369) into Eq. (14.374) gives:

$$\theta_{C-H_{acetylene},H_2MO} = 48.71° \tag{14.375}$$

Then, the distance $d_{C-H_{acetylene},H_2MO}$ along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by

$$d_{C-H_{acetylene},H_2MO} = a\cos\theta_{C-H_{acetylene},H_2MO} \tag{14.376}$$

Substitution of Eqs. (14.365) and (14.375) into Eq. (14.376) gives:

$$d_3 : d_{C-H_{acetylene},H_2MO} = 0.98145a_0 = 5.19359\ X\ 10^{-11}\ m \tag{14.377}$$

The distance $d_{C-H_{acetylene}2sp^3HO}$ along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals is given by

$$d_{C-H_{acetylene}2sp^3HO} = c' - d_{C-H_{acetylene},H_2MO} \tag{14.378}$$

Substitution of Eqs. (14.366) and (14.377) into Eq. (14.378) gives:

$$d_4 : d_{C-H_{acetylene}2sp^3HO} = 0.01427a_0 = 7.55329\ X\ 10^{-13}\ m \tag{14.379}$$

with the $C \equiv C$ triple bond along one axis, the minimum energy is obtained with the $C-H$-bond MO at a maximum separation. Thus, the bond angle $\theta_{C\equiv C-H}$ between the internuclear axis of the $C \equiv C$ bond and the H atom of the CH groups is

$$\theta_{C\equiv C-H} = 180° \tag{14.380}$$

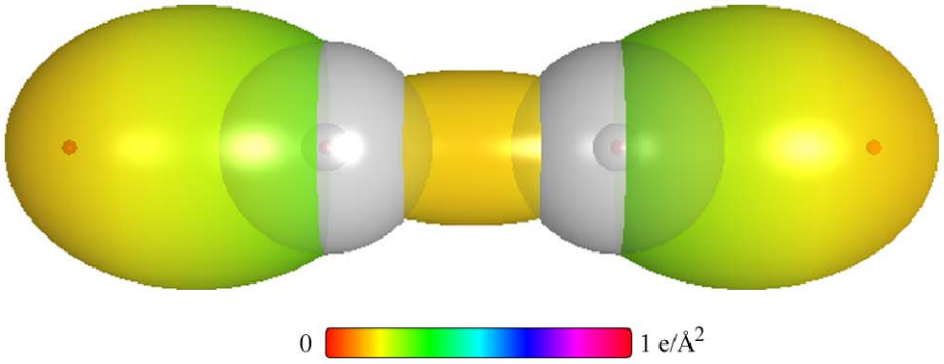
The experimental angle between the $C \equiv C-H$ bonds is [6]:

$$\theta_{C\equiv C-H} = 180° \tag{14.381}$$

The $CHCH$ MO shown in Figure 14.12 was rendered using these parameters.

The charge-density in the $C \equiv C$-bond MO is increased by a factor of 0.25 per bond with the formation of the $C_{acetylene}2sp^3$ HOs each having a smaller radius. Using the orbital composition of the CH groups (Eq. (14.361)) and the $C \equiv C$-bond MO (Eq. (14.337)), the radii of $C1s = 0.17113a_0$ (Eq. (10.51)) and $C_{acetylene}2sp^3 = 0.83008a_0$ (Eq. (14.339)) shells, and the parameters of the $C \equiv C$-bond (Eqs. (13.3-13.4), (14.346-14.348), and (14.350-14.360)), the parameters of the $C-H$-bond MOs (Eqs. (13.3-13.4), (14.365-14.367), and (14.369-14.379)), and the bond-angle parameter (Eqs. (14.380-14.381)), the charge-density of the $CHCH$ MO comprising the linear combination of two $C-H$-bond MOs and a $C \equiv C$-bond MO bridging the two CH groups is shown in Figure 14.12. Each $C-H$-bond MO comprises a H_2-type ellipsoidal MO and a $C_{acetylene}2sp^3$ HO having the dimensional diagram shown in Figure 14.11. The $C \equiv C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{acetylene}2sp^3$ HOs having the dimensional diagram also shown in Figure 14.11.

Figure 14.12. $CHCH$ MO comprising the linear combination of two $C-H$ -bond MOs and a $C\equiv C$ -bond MO. (A) Color scale, translucent view of the charge-density of the $C\equiv C$ -bond MO with the $C_{acetylene}2sp^3$ HOs shown transparently. The $C\equiv C$ -bond MO comprises a H_2 -type ellipsoidal MO bridging two sets of three $C_{acetylene}2sp^3$ HOs. For each $C-H$ and the $C\equiv C$ bond, the ellipsoidal surface of the H_2 -type ellipsoidal MO that transitions to the $C_{acetylene}2sp^3$ HO, the $C_{acetylene}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown. (B)-(D) Translucent view high-lighting the $C\equiv C$ -bond MO and end-on view of the charge-density of the $CHCH$ MO, respectively.



ENERGIES OF THE CH GROUPS

The energies of each CH group of acetylene are given by the substitution of the semiprincipal axes (Eqs. (14.365-14.366) and (14.369)) into the energy equations of hydrogen carbide (Eqs. (13.510-13.514)), with the exception that two times $E_T\left(C\equiv C,2sp^3\right)$ (Eq. (14.342)) is subtracted from $E_T\left(CH\right)$ in Eq. (13.514).

$$V_e=\left(0.91771\right)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=-40.62396\ eV \tag{14.382}$$

$$V_p=\frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}=13.66428\ eV \tag{14.383}$$

$$T=\left(0.91771\right)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=13.65796\ eV \tag{14.384}$$

$$V_m=\left(0.91771\right)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=-6.82898\ eV \tag{14.385}$$

$$E_{T_{acetylene}}\left(CH\right)=\left(\begin{array}{l}-\dfrac{e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+c'}{a-c'}-1\right]\\ -14.63489\ eV-\left(-3.13026\ eV\right)\end{array}\right)=-31.63532\ eV \tag{14.386}$$

where $E_{T_{acetylene}}\left(CH\right)$ is given by Eq. (14.362) which is reiteratively matched to Eq. (13.75) within five-significant-figure round off error.

VIBRATION OF THE ^{12}CH GROUPS

The vibrational energy levels of CH in acetylene may be solved using the methods given in the Vibration and Rotation of CH section.

THE DOPPLER ENERGY TERMS OF THE ^{12}CH GROUPS

The equations of the radiation reaction force of the CH groups in acetylene are the same as those of the hydrogen carbide radical with the substitution of the CH -group parameters. Using Eq. (13.477), the angular frequency of the reentrant oscillation in the transition state is:

$$\omega = \sqrt{\frac{0.75e^2}{4\pi\varepsilon_0 b^3}} = 3.08370\ X\ 10^{16}\ rad/s \tag{14.387}$$

where b is given by Eq. (14.369). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)):

$$\overline{E}_K = \hbar\omega = \hbar 3.08370\ X\ 10^{16}\ rad/s = 20.29747\ eV \tag{14.388}$$

In Eq. (11.181), substitution of $E_T\left(H_2\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each H_2-type MO, for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.388) for $\overline{E}_K$ gives the Doppler energy of the electrons for the reentrant orbit:

$$\overline{E}_D \cong E_{h\nu}\sqrt{\frac{2\overline{E}_K}{Mc^2}} = -31.63537\ eV\sqrt{\frac{2e(20.29747\ eV)}{m_e c^2}} = -0.28197\ eV \tag{14.389}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of CH due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\overline{E}_{osc}$, is given by the sum of the corresponding energies, $\overline{E}_D$ given by Eq. (14.389) and $\overline{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of each $C-H$ bond. Using ω_e given by Eq. (13.458) for $\overline{E}_{Kvib}$ of the transition state, $\overline{E}_{acetylene\ osc}\left({}^{12}CH\right)$ is:

$$\overline{E}_{acetylene\ osc}\left({}^{12}CH\right) = \overline{E}_D + \overline{E}_{Kvib} = \overline{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{14.390}$$

$$\overline{E}_{acetylene\ osc}\left({}^{12}CH\right) = -0.28197\ eV + \frac{1}{2}(0.35532\ eV) = -0.10430\ eV \tag{14.391}$$

TOTAL AND DIFFERENCE ENERGIES OF THE ${}^{12}CH$ GROUPS

$E_{acetyleneT+osc}\left({}^{12}CH\right)$, the total energy of each ${}^{12}CH$ group including the Doppler term, is given by the sum of $E_{T_{acetylene}}(CH)$ (Eq. (14.386)) and $\overline{E}_{acetylene\ osc}\left({}^{12}CH\right)$ given by Eq. (14.391).

$$\begin{aligned} E_{acetyleneT+osc}\left({}^{12}CH\right) &= \begin{pmatrix} V_e + T + V_m + V_p + E\left(C, 2sp^3\right) \\ -2E_T\left(C \equiv C, 2sp^3\right) + \overline{E}_{acetylene\ osc}\left({}^{12}CH\right) \end{pmatrix} \\ &= E_{T_{acetylene}}(CH) + \overline{E}_{acetylene\ osc}\left({}^{12}CH\right) \end{aligned} \tag{14.392}$$

$$\begin{aligned} E_{acetyleneT+osc}\left({}^{12}CH\right) &= \left\{ \begin{pmatrix} \left(\frac{-e^2}{8\pi\varepsilon_0 c'}\right)\left[(0.91771)\left(2 - \frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'} - 1\right] \\ -14.63489\ eV - (-3.13026\ eV) \end{pmatrix} \right. \\ &\quad \left. - \left((31.63536831\ eV)\sqrt{\frac{2\hbar\sqrt{\frac{3}{4}\frac{e^2}{4\pi\varepsilon_o b^3}}}{m_e c^2}} - \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \right) \right\} \\ &= -31.63537\ eV - \left(0.28197\ eV - \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \end{aligned} \tag{14.393}$$

From Eqs. (14.391-14.393), the total energy of each ${}^{12}CH$ is:

$$\begin{aligned} E_{acetyleneT+osc}\left({}^{12}CH\right) &= -31.63537\ eV + \overline{E}_{acetylene\ osc}\left({}^{12}CH\right) \\ &= -31.63537\ eV - \left(0.28197\ eV - \frac{1}{2}(0.35532\ eV)\right) = -31.73967\ eV \end{aligned} \tag{14.394}$$

where ω_e given by Eq. (13.458) was used for the $\hbar\sqrt{\frac{k}{\mu}}$ term.

The total energy for each hydrogen carbide radical given by Eq. (13.485) is:

$$\begin{aligned} E_{radicalT+osc}\left({}^{12}CH\right) &= -31.63537\ eV + \bar{E}_{radicalosc}\left({}^{12}CH\right) \\ &= -31.63537\ eV - 0.24966\ eV + \frac{1}{2}\left(0.35532\ eV\right) \\ &= -31.70737\ eV \end{aligned} \tag{14.395}$$

The difference in energy between the CH groups and the hydrogen carbide radical $\Delta E_{T+osc}\left({}^{12}CH\right)$ is given by two times the difference between Eqs. (14.394) and (14.395).

$$\begin{aligned} \Delta E_{T+osc}\left({}^{12}CH\right) &= 2\left(E_{acetyleneT+osc}\left({}^{12}CH\right) - E_{radicalT+osc}\left({}^{12}CH\right)\right) \\ &= 2\left(-31.73967\ eV - \left(-31.70737\ eV\right)\right) \\ &= -0.06460\ eV \end{aligned} \tag{14.396}$$

SUM OF THE ENERGIES OF THE $C \equiv C$ σ MO AND THE HOS OF ACETYLENE

The energy components of V_e, V_p, T, V_m, and E_T of the $C \equiv C$-bond MO are the same as those of the CH MO except that each term is multiplied by three corresponding to the triple bond and the energy term corresponding to the $C_{acetylene}2sp^3$ HOs in the equation for E_T is positive. The energies of each $C \equiv C$-bond MO are given by the substitution of the semiprincipal axes (Eqs. (14.346-14.347) and (14.350)) into three times the energy equations of the CH MO (Eqs. (13.449-13.453)), with the exception that $E\left(C, 2sp^3\right)$ in Eq. (13.453) is positive and given by Eq. (14.341).

$$V_e = 3\left(0.91771\right)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -182.53826\ eV \tag{14.397}$$

$$V_p = 3\frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 35.97770\ eV \tag{14.398}$$

$$T = 3\left(0.91771\right)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 70.90876\ eV \tag{14.399}$$

$$V_m = 3\left(0.91771\right)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -35.45438\ eV \tag{14.400}$$

$$E_T\left(C \equiv C, \sigma\right) = -\frac{3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2 - \frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'} - 1\right] + 16.20002\ eV = -94.90616\ eV \tag{14.401}$$

where $E_T\left(C \equiv C, \sigma\right)$ is the total energy of the $C \equiv C$ σ MO given by Eq. (14.343) which is reiteratively matched to three times Eq. (13.75) within five-significant-figure round off error.

The total energy of the $C \equiv C$-bond MO, $E_T\left(C \equiv C\right)$, is given by the sum of two times $E_T\left(C \equiv C, 2sp^3\right)$, the energy change of each $C2sp^3$ shell due to the decrease in radius with the formation of the $C \equiv C$-bond MO (Eq. (14.342)), and $E_T\left(C \equiv C, \sigma\right)$, the σ MO contribution given by Eq. (14.344).

$$\begin{aligned} E_T\left(C \equiv C\right) &= 2E_T\left(C \equiv C, 2sp^3\right) + E_T\left(C \equiv C, \sigma\right) \\ &= \left(\begin{array}{l} 2\left(-1.56513\ eV\right) + \\ \left(-\frac{2e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2 - \frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'} - 1\right] + 16.20002\ eV\right) \end{array}\right) \\ &= 2\left(-1.56513\ eV\right) + \left(-94.90610\ eV\right) \\ &= -98.03637\ eV \end{aligned} \tag{14.402}$$

VIBRATION OF ACETYLENE

The vibrational energy levels of $CHCH$ may be solved as two equivalent coupled harmonic oscillators with a bridging harmonic oscillator by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

THE DOPPLER ENERGY TERMS OF THE $C \equiv C$-BOND MO OF ACETYLENE

The equations of the radiation reaction force of the $C \equiv C$-bond MO are given by Eq. (14.231), except that the $C \equiv C$-bond MO parameters are used. The angular frequency of the reentrant oscillation in the transition state is:

$$\omega = \sqrt{\frac{0.5e^2}{4\pi\varepsilon_0 a^3}} = 2.00186\ X\ 10^{16}\ rad/s \tag{14.403}$$

where a is given by Eq. (14.346). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K = \hbar\omega = \hbar 2.00186\ X\ 10^{16}\ rad/s = 13.17659\ eV \tag{14.404}$$

In Eq. (11.181), substitution of $E_T(C \equiv C)/3$ (Eq. (14.402)) for E_{hv}, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.404) for $\bar{E}_K$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$\bar{E}_D \cong E_{hv}\sqrt{\frac{2\bar{E}_K}{Mc^2}} = -32.67879\ eV\sqrt{\frac{2e(13.17659\ eV)}{m_e c^2}} = -0.23468\ eV \tag{14.405}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $C \equiv C$-bond MO due to the reentrant orbit of the bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (14.405) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of the $C \equiv C$ bond. Using the experimental $C \equiv C$ $E_{vib}(\upsilon_3)$ of 3374 cm^{-1} $(0.41833\ eV)$ [6] for $\bar{E}_{Kvib}$ of the transition state having three bonds, $\bar{E}'_{osc}(C \equiv C, \sigma)$ per bond is:

$$\bar{E}'_{osc}(C \equiv C, \sigma) = \bar{E}_D + \bar{E}_{Kvib} = \bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{14.406}$$

$$\bar{E}'_{osc}(C \equiv C, \sigma) = -0.23468\ eV + \frac{1}{2}(0.41833\ eV) = -0.02551\ eV \tag{14.407}$$

Given that the vibration and reentrant oscillation is for three $C-C$ bonds of the $C \equiv C$ triple bond, $\bar{E}_{acetylene\ osc}(C \equiv C, \sigma)$, is:

$$\begin{aligned}\bar{E}_{acetylene\ osc}(C \equiv C, \sigma) &= 3\left(\bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)\\ &= 3\left(-0.23468\ eV + \frac{1}{2}(0.41833\ eV)\right)\\ &= -0.07654\ eV\end{aligned} \tag{14.408}$$

TOTAL ENERGIES OF THE $C \equiv C$-BOND MO OF ACETYLENE

$E_{T+osc}(C \equiv C)$, the total energy of the $C \equiv C$-bond MO including the Doppler term, is given by the sum of $E_T(C \equiv C)$ (Eq. (14.402)) and $\bar{E}_{acetylene\ osc}(C \equiv C, \sigma)$ given by Eq. (14.408).

$$\begin{aligned}E_{T+osc}(C \equiv C) &= \begin{pmatrix} V_e + T + V_m + V_p - E(C_{acetylene}, 2sp^3) \\ +2E_T(C \equiv C, 2sp^3) + \bar{E}_{acetylene\ osc}(C \equiv C, \sigma)\end{pmatrix}\\ &= E_T(C \equiv C, \sigma) + 2E_T(C \equiv C, 2sp^3) + \bar{E}_{acetylene\ osc}(C \equiv C, \sigma)\\ &= E_T(C \equiv C) + \bar{E}_{acetylene\ osc}(C \equiv C, \sigma)\end{aligned} \tag{14.409}$$

$$E_{T+osc}(C \equiv C) = \left\{\begin{pmatrix} \left(\frac{-3e^2}{8\pi\varepsilon_0 c'}\right)\left[(0.91771)\left(2 - \frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'} - 1\right] \\ -E(C_{acetylene}, 2sp^3) + 2E_T(C \equiv C, 2sp^3)\end{pmatrix}\right\}$$
$$\left\{\begin{pmatrix} 1 + (3)\left(\frac{1}{3}\right)\sqrt{\frac{2\hbar\sqrt{\frac{1}{2}\frac{e^2}{4\pi\varepsilon_0 a^3}}}{m_e c^2}} \end{pmatrix} + 3\left(\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)\right\} \tag{14.410}$$

$$= -98.03637\ eV - 3\left(0.23468\ eV - \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)$$

From Eqs. (14.408-14.410), the total energy of the $C \equiv C$ -bond MO is:

$$\begin{aligned} E_{T+osc}\left(C \equiv C\right) &= -94.90610\ eV + 2E_T\left(C \equiv C, 2sp^3\right) + \bar{E}_{acetylene\ osc}\left(C \equiv C, \sigma\right) \\ &= -94.90610\ eV + 2\left(-1.56513\ eV\right) - 3\left(0.23468\ eV - \frac{1}{2}\left(0.41833\ eV\right)\right) \\ &= -98.11291\ eV \end{aligned} \tag{14.411}$$

where the experimental E_{vib} was used for the $\hbar\sqrt{\frac{k}{\mu}}$ term.

BOND ENERGY OF THE $C \equiv C$ BOND OF ACETYLENE

As in the case of $^{12}CH_2$ and ^{14}NH, the dissociation of the $C \equiv C$ bond forms three unpaired electrons per central atom wherein the magnetic moments cannot all cancel. The energy per atom $E(magnetic)$ is given by Eq. (13.524). Thus, the dissociation energy of the $C \equiv C$ bond of $CHCH$, $E_D\left(HC \equiv CH\right)$, is given by six times $E\left(C, 2sp^3\right)$ (Eq. (14.146)), the initial energy of each $C2sp^3$ HO of each CH radical that forms the triple $C \equiv C$ bond, minus the sum of $\Delta E_{T+osc}\left(^{12}CH\right)$ (Eq. (14.396)), the energy change going from the hydrogen carbide radicals to the CH groups of acetylene, $E_{T+osc}\left(C \equiv C\right)$ (Eq. (14.411)), and two times $E(magnetic)$ given by Eq. (13.524). Thus, the dissociation energy of the $C \equiv C$ bond of $CHCH$, is:

$$\begin{aligned} E_D\left(HC \equiv CH\right) &= 6\left(E\left(C, 2sp^3\right)\right) - \left(\Delta E_{T+osc}\left(^{12}CH\right) + E_{T+osc}\left(C \equiv C\right) + 2E(magnetic)\right) \\ &= 6\left(-14.63489\ eV\right) - \left(-0.06460\ eV - 98.11291\ eV + 0.29606\ eV\right) \\ &= 6\left(-14.63489\ eV\right) - \left(-97.88145\ eV\right) = 10.07212\ eV \end{aligned} \tag{14.412}$$

The experimental dissociation energy of the $C \equiv C$ bond of $CHCH$ is [7]:

$$E_D\left(HC \equiv CH\right) = 10.0014\ eV \tag{14.413}$$

The results of the determination of bond parameters of $CHCH$ are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

BENZENE MOLECULE (C_6H_6)

The benzene molecule C_6H_6 is formed by the reaction of three ethylene molecules:

$$3CH_2CH_2 \rightarrow C_6H_6 + 3H_2 \tag{14.414}$$

C_6H_6 can be solved using the same principles as those used to solve ethylene wherein the $2s$ and $2p$ shells of each C hybridize to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. Each $2sp^3$ HO of each carbon atom initially has four unpaired electrons. Thus, the $6H$ atomic orbitals (AOs) of benzene contribute six electrons and the six sp^3-hybridized carbon atoms contribute twenty-four electrons to form six $C-H$ bonds and six $C=C$ bonds. Each $C-H$ bond has two paired electrons with one donated from the H AO and the other from the $C2sp^3$ HO. Each $C=C$ bond comprises a linear combination of a factor of 0.75 of four paired electrons (three electrons) from two sets of two $C2sp^3$ HOs of the participating carbon atoms. Each $C-H$ and each $C=C$ bond comprises a linear combination of one and two diatomic H_2-type MOs developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section, respectively.

FORCE BALANCE OF THE $C=C$-BOND MO OF BENZENE

C_6H_6 can be considered a linear combination of three ethylene molecules wherein a $C-H$ bond of each CH_2 group of $H_2C=CH_2$ is replaced by a $C=C$ bond to form a six-member ring of carbon atoms. The solution of the ethylene molecule is given in the Ethylene Molecule (CH_2CH_2) section. Before forming ethylene groups, the $2sp^3$ hybridized orbital arrangement of each carbon atom is given by Eq. (14.140). The sum $E_T\left(C, 2sp^3\right)$ of calculated energies of C, C^+, C^{2+}, and C^{3+} is given by Eq. (14.141). The radius r_{2sp^3} of the $C2sp^3$ shell is given by Eq. (14.142). The Coulombic energy $E_{Coulomb}\left(C, 2sp^3\right)$ and the energy $E\left(C, 2sp^3\right)$ of the outer electron of the $C2sp^3$ shell are given by Eqs. (14.143) and (14.146), respectively. Two CH_2 radicals bond to form CH_2CH_2 by forming a MO between the two pairs of remaining $C2sp^3$-HO electrons of the two carbon

atoms. However, in this case, the sharing of electrons between four $C2sp^3$ HOs to form a MO comprising four spin-paired electrons permits each $C2sp^3$ HO to decrease in radius and energy. The $C=C$-bond MO is a prolate-spheroidal-MO surface that cannot extend into $C2sp^3$ HO for distances shorter than the radius of the $C2sp^3$ shell of each atom. Thus, the MO surface comprises a partial prolate spheroid in between the carbon nuclei and is continuous with the $C2sp^3$ shell at each C atom. The energy of the H_2-type ellipsoidal MO is matched to that of each $C2sp^3$ shell. As in the case of previous examples of energy-matched MOs such as those of OH, NH, CH, the $C=O$-bond MO of CO_2, and the $C-C$-bond MO of CH_3CH_3, the $C=C$-bond MO of ethylene must comprise 75% of a H_2-type ellipsoidal MO in order to match potential, kinetic, and orbital energy relationships. Thus, the $C=C$-bond MO must comprise a linear combination of two MOs wherein each comprises two $C2sp^3$ HOs and 75% of a H_2-type ellipsoidal MO divided between the $C2sp^3$ HOs:

$$2\left(2\ C2sp^3 + 0.75\ H_2\ MO\right) \rightarrow C=C-bond\ MO \tag{14.415}$$

The linear combination of each H_2-type ellipsoidal MO with each $C2sp^3$ HO further comprises an excess 25% charge-density contribution from each $C2sp^3$ HO to the $C=C$-bond MO to achieve an energy minimum. The force balance of the $C=C$-bond MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.415) and the energy matching condition between the $C2sp^3$-HO components of the MO.

The sharing of electrons between two pairs of $C2sp^3$ HOs to form a $C=C$-bond MO permits each participating hybridized orbital to decrease in radius and energy. The sum $E_T\left(C_{ethylene}, 2sp^3\right)$ of calculated energies of $C2sp^3$, C^+, C^{2+}, and C^{3+} is given by Eq. (14.243). In order to further satisfy the potential, kinetic, and orbital energy relationships, each participating $C2sp^3$ HO donates an excess of 25% of its electron density to the $C=C$-bond MO to form an energy minimum. By considering this electron redistribution in the ethylene molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{ethylene\,2sp^3}$ of the $C2sp^3$ shell of ethylene calculated from the Coulombic energy is given by Eq. (14.244). The Coulombic energy $E_{Coulomb}\left(C_{ethylene}, 2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is given by Eq. (14.245). The energy $E\left(C_{ethylene}, 2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is given by Eq. (14.246). $E_T\left(C=C, 2sp^3\right)$ (Eq. (14.247)), the energy change of each $C2sp^3$ shell with the formation of the $C=C$-bond MO is given by the difference between $E\left(C_{ethylene}, 2sp^3\right)$ and $E\left(C, 2sp^3\right)$.

Consider the case where three sets of $C=C$-bond MOs form bonds between the two carbon atoms of each molecule to form a six-member ring such that the six resulting bonds comprise eighteen paired electrons. Each bond comprises a linear combination of two MOs wherein each comprises two $C2sp^3$ HOs and 75% of a H_2-type ellipsoidal MO divided between the $C2sp^3$ HOs:

$$\begin{pmatrix} 3\left(2\ C2sp^3 + 0.75\ H_2\ MO\right) \rightarrow 3\left(C \overset{4e}{=} C\right) - ethylene-type-bond\ MO \\ \rightarrow 6\left(C \overset{3e}{=} C\right) - bond\ MO\ of\ benzene \end{pmatrix} \tag{14.416}$$

The linear combination of each H_2-type ellipsoidal MO with each $C2sp^3$ HO further comprises an excess 25% charge-density contribution per bond from each $C2sp^3$ HO to the $C=C$-bond MO to achieve an energy minimum. Thus, the dimensional parameters of each bond $C=C$-bond are determined using the same equations as those used to determine the same parameters of the $C=C$-bond MO of ethylene (Eqs. (14.242-14.268)) while matching the boundary conditions of the structure of benzene. The energies of each $C=C$ bond of benzene are also determined using the same equations as those of ethylene with the parameters of benzene. The result is that the energies are essentially given as 0.75 times the energies of the $C=C$-bond MO of ethylene (Eqs. (14.251-14.253) and (14.319-14.333)).

The derivation of the dimensional parameters of benzene follows the same procedure as the determination of those of ethylene. As in the case of ethylene, each H_2-type ellipsoidal MO comprises 75% of the $C=C$-bond MO shared between two $C2sp^3$ HOs corresponding to the electron charge density in Eq. (11.65) of $\frac{-0.75e}{2}$. But, the additional 25% charge-density contribution to each bond of the $C=C$-bond MO causes the electron charge density in Eq. (11.65) to be $\frac{-e}{2} = -0.5e$. The corresponding force constant k' is given by Eq. (14.152). In addition, the energy matching at all six $C2sp^3$ HOs further requires that k' be corrected by a hybridization factor (Eq. (13.430)) as in the case of ethylene, expect that the constraint that the bonds connect a six-member ring of $C=C$ bonds of benzene rather two $C2sp^3$ HOs of ethylene decreases the hybridization factor of benzene compared to that of ethylene (Eq. (14.248)).

Since the energy of each H_2-type ellipsoidal MO is matched to that of all the continuously connected $C_{benzene}2sp^3$ HOs, the hybridization-energy-matching factor is 0.85252. Hybridization with 25% electron donation to each $C=C$-bond gives rise to the $C_{benzene}2sp^3$ HO-shell Coulombic energy $E_{Coulomb}\left(C_{benzene},2sp^3\right)$ given by Eq. (14.245). The corresponding hybridization factor is given by the ratio of $15.95955\ eV$, the magnitude of $E_{Coulomb}\left(C_{benzene},2sp^3\right)$ given by Eq. (14.245), and $13.605804\ eV$, the magnitude of the Coulombic energy between the electron and proton of H given by Eq. (1.264). The hybridization energy factor $C_{benzeneC2sp^3HO}$ is:

$$C_{benzeneC2sp^3HO}=\frac{\frac{e^2}{8\pi\varepsilon_0 a_0}}{\frac{e^2}{8\pi\varepsilon_0 r_{benzene2sp^3}}}=\frac{\frac{e^2}{8\pi\varepsilon_0 a_0}}{\frac{e^2}{8\pi\varepsilon_0 0.85252a_0}}=\frac{13.605804\ eV}{15.95955\ eV}=0.85252 \tag{14.417}$$

Thus, the force constant k' to determine the ellipsoidal parameter c' in terms of the central force of the foci (Eq. (11.65)) is given by:

$$k'=C_{benzeneC2sp^3HO}\frac{(0.5)2e^2}{4\pi\varepsilon_0}=0.85252\frac{(0.5)2e^2}{4\pi\varepsilon_0} \tag{14.418}$$

The distance from the origin to each focus c' is given by substitution of Eq. (14.418) into Eq. (13.60). Thus, the distance from the origin of the component of the double $C=C$-bond MO to each focus c' is given by

$$c'=a\sqrt{\frac{\hbar^2 4\pi\varepsilon_0}{(0.85252)m_e e^2 a}}=\sqrt{\frac{aa_0}{0.85252}} \tag{14.419}$$

The internuclear distance from Eq. (14.419) is:

$$2c'=2\sqrt{\frac{aa_0}{0.85252}} \tag{14.420}$$

The length of the semiminor axis of the prolate spheroidal $C=C$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of the $C=C$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the $C=C$-bond MO are solved.

The general equations for the energy components of V_e, V_p, T, V_m, and E_T of the $C=C$-bond MO of benzene are the same as those of the CH_2CH_2 MO except that energy of the $C_{benzene}2sp^3$ HO is used and the hybridization factor is given by Eq. (14.417). Using Eqs. (14.251) and (14.417), $E_T\left(C=C,\sigma\right)$ is given by:

$$E_T\left(C=C,\sigma\right)=E_T+E\left(C_{benzene},2sp^3\right)-E\left(C_{benzene},2sp^3\right)=-\frac{2e^2}{8\pi\varepsilon_0 c'}\left[(0.85252)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right] \tag{14.421}$$

The total energy term of the double $C=C$-bond MO is given by the sum of the two H_2-type ellipsoidal MOs given by Eq. (11.212). To match this boundary condition, $E_T\left(C=C,\sigma\right)$ given by Eq. (14.421) is set equal to two times Eq. (13.75):

$$E_T\left(C=C,\sigma\right)=-\frac{2e^2}{8\pi\varepsilon_0 c'}\left[(0.85252)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]=-63.27074\ eV \tag{14.422}$$

From the energy relationship given by Eq. (14.422) and the relationship between the axes given by Eqs. (14.419-14.420) and (13.62-13.63), the dimensions of the $C=C$-bond MO can be solved.

Substitution of Eq. (14.419) into Eq. (14.422) gives:

$$\frac{2e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{0.85252}}}\left[(0.85252)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{0.85252}}}{a-\sqrt{\frac{aa_0}{0.85252}}}-1\right]=e63.27074 \tag{14.423}$$

The most convenient way to solve Eq. (14.423) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a=1.47348a_0=7.79733\ X\ 10^{-11}\ m \tag{14.424}$$

Substitution of Eq. (14.424) into Eq. (14.4129) gives:

$$c'=1.31468a_0=6.95699\ X\ 10^{-11}\ m \tag{14.425}$$

The internuclear distance given by multiplying Eq. (14.425) by two is:

$$2c'=2.62936a_0=1.39140\ X\ 10^{-10}\ m \tag{14.426}$$

The experimental bond distance is [3] :

$$2c' = 1.339\ X\ 10^{-10}\ m \tag{14.427}$$

Substitution of Eqs. (14.424-14.425) into Eq. (13.62) gives:

$$b = c = 0.66540a_0 = 3.52116\ X\ 10^{-11}\ m \tag{14.428}$$

Substitution of Eqs. (14.424-14.425) into Eq. (13.63) gives:

$$e = 0.89223 \tag{14.429}$$

The nucleus of the C atoms comprise the foci of the H_2-type ellipsoidal MO. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $C_{benzene}2sp^3$ HO are given by Eqs. (13.84-13.95) and (13.261-13.270). Each benzene carbon atom contributes $(0.75)(-1.13380\ eV) = -0.85035\ eV$ (Eqs. (14.483) and (14.493)) to each of the two $C \overset{3e}{=} C$-bond MOs and $(0.5)(-1.13380\ eV) = -0.56690\ eV$ (Eq. (14.467)) to the corresponding $C-H$-bond MO. The energy contribution due to the charge donation at each carbon superimposes linearly. The radius of $r_{benzene2sp^3} = 0.79597a_0$ is calculated using Eq. (14.518) using the total energy donation to each bond with which it is participates in bonding. The polar intersection angle θ' is given by Eq. (13.261) where $r_n = r_{benzene2sp^3} = 0.79597a_0$ is the radius of the $C_{benzene}2sp^3$ shell. Substitution of Eqs. (14.424-14.425) into Eq. (13.261) gives:

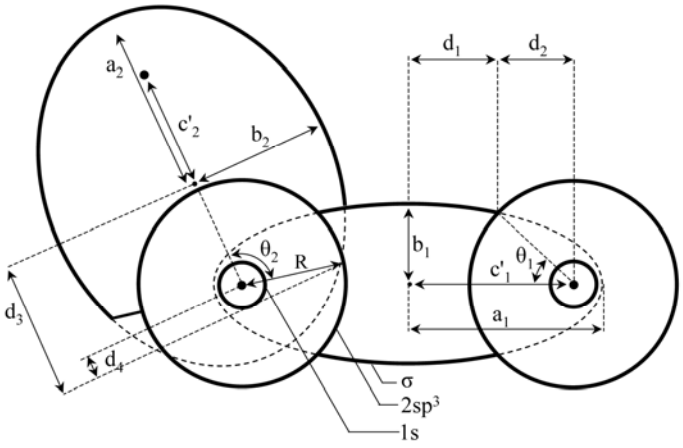
$$\theta' = 134.24° \tag{14.430}$$

Then, the angle $\theta_{C=C_{benzene}2sp^3HO}$ the radial vector of the $C2sp^3$ HO makes with the internuclear axis is:

$$\theta_{C=C_{benzene}2sp^3HO} = 180° - 134.24° = 45.76° \tag{14.431}$$

as shown in Figure 14.13.

Figure 14.13. The cross section of one $C=C$-bond MO (σ MO) and one $C-H$-bond MO of benzene showing the axes, angles, and point of intersection of each H_2-type ellipsoidal MO with the corresponding $C_{benzene}2sp^3$ HO. The continuation of each H_2-type-ellipsoidal-MO basis element of the $C=C$ bond and the $C-H$-bond beyond the intersection point with each $C_{benzene}2sp^3$ shell and σ MO is shown as dashed since each only serves to solve the energy match with the $C_{benzene}2sp^3$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of each intersection point. The actual charge density is shown by the solid lines. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, $d_1 : d_{C=C_{benzene},H_2MO}$, $\theta_1 : \theta_{C=C_{benzene}2sp^3HO}$, $d_2 : d_{C=C_{benzene}2sp^3HO}$, $R : r_{benzeneC2sp^3}$, $d_3 : d_{C-H_{benzene},H_2MO}$, $\theta_2 : \theta_{C-H_{benzene}2sp^3HO}$, and $d_4 : d_{C-H_{benzene}2sp^3HO}$.



Consider the right-hand intersection point. The Cartesian **i**-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian **j**-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{C=C_{benzene},H_2MO}$ satisfies the following relationship:

$$r_{benzene2sp^3} \sin\theta_{C=C_{benzene}2sp^3HO} = 0.79597a_0 \sin\theta_{C=C_{benzene}2sp^3HO} = b\sin\theta_{C=C_{benzene},H_2MO} \tag{14.432}$$

such that

$$\theta_{C=C_{benzene},H_2MO} = \sin^{-1}\frac{0.79597a_0 \sin\theta_{C=C_{benzene}2sp^3HO}}{b} = \sin^{-1}\frac{0.79597a_0 \sin 45.76°}{b} \tag{14.433}$$

with the use of Eq. (14.431). Substitution of Eq. (14.428) into Eq. (14.433) gives:

$$\theta_{C=C_{benzene},H_2MO} = 58.98° \tag{14.434}$$

Then, the distance $d_{C=C_{benzene},H_2MO}$ along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$d_{C=C_{benzene},H_2MO} = a\cos\theta_{C=C_{benzene},H_2MO} \tag{14.435}$$

Substitution of Eqs. (14.424) and (14.434) into Eq. (14.435) gives:

$$d_{C=C_{benzene},H_2MO} = 0.75935a_0 = 4.01829\ X\ 10^{-11}\ m \tag{14.436}$$

The distance $d_{C=C_{benzene}2sp^3HO}$ along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals is given by

$$d_{C=C_{benzene}2sp^3HO} = c' - d_{C=C_{benzene},H_2MO} \tag{14.437}$$

Substitution of Eqs. (14.425) and (14.436) into Eq. (14.437) gives:

$$d_{C=C_{benzene}2sp^3HO} = 0.55533a_0 = 2.93870\ X\ 10^{-11}\ m \tag{14.438}$$

FORCE BALANCE OF THE CH MOS OF BENZENE

Benzene can also be considered as comprising chemical bonds between six CH radicals wherein each radical comprises a chemical bond between carbon and hydrogen atoms. The solution of the parameters of CH is given in the Hydrogen Carbide (CH) section. Each $C-H$ bond of CH having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of 75% H_2-type ellipsoidal MO and 25% $C2sp^3$ HO as given by Eq. (13.439):

$$1\ C2sp^3 + 0.75\ H_2\ MO \rightarrow CH\ MO \tag{14.439}$$

The proton of the H atom and the nucleus of the C atom are along each internuclear axis and serve as the foci. As in the case of H_2, the $C-H$-bond MO is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $C2sp^3$ HO for distances shorter than the radius of the $C2sp^3$ shell since it is energetically unfavorable. Thus, each MO surface comprises a prolate spheroid at the H proton that is continuous with the $C2sp^3$ shell at the C atom whose nucleus serves as the other focus.

The force balance of the CH MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.439) and the energy matching condition between the hydrogen and $C2sp^3$ HO components of the MO. The force constant k' to determine the ellipsoidal parameter c' of each H_2-type-ellipsoidal-MO component of the CH MO in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus c' is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $C-H$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the CH MO are solved.

Consider the formation of the double $C=C$-bond MOs of benzene wherein ethylene formed from two CH_2 radicals, each having a $C2sp^3$ shell with an energy given by Eq. (14.146), serves as a basis element. The energy components of V_e, V_p, T, V_m, and E_T are the same as those of the hydrogen carbide radical, except that $E_T\left(C=C,2sp^3\right)$ is subtracted from $E_T\left(CH\right)$ of Eq. (13.495). As in the case of the CH_2 groups of ethylene (Eq. (14.270)), the subtraction of the energy change of the $C2sp^3$ shell per H with the formation of the $C=C$-bond MO matches the energy of each $C-H$-bond MO to the decrease in the energy of the corresponding $C2sp^3$ HO. Using Eqs. (13.431) and (14.247), $E_{T_{benzene}}\left(CH\right)$ is given by:

$$E_{T_{benzene}}\left(CH\right) = E_T + E\left(C,2sp^3\right) - E_T\left(C=C,2sp^3\right) = \begin{pmatrix} -\frac{e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right] \\ -14.63489\ eV-\left(-1.13379\ eV\right)\end{pmatrix} \tag{14.440}$$

$E_{T_{benzene}}\left(CH\right)$ given by Eq. (14.440) is set equal to the energy of the H_2-type ellipsoidal MO given by Eq. (13.75).

$$E_{T_{benzene}}\left(CH\right) = \begin{pmatrix} -\frac{e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right] \\ -14.63489\ eV-\left(-1.13379\ eV\right)\end{pmatrix} = -31.63537\ eV \tag{14.441}$$

From the energy relationship given by Eq. (14.441) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the CH MO can be solved.

Substitution of Eq. (13.60) into Eq. (14.441) gives:

$$\frac{e^2}{8\pi\varepsilon_0\sqrt{\frac{2aa_0}{3}}}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{2aa_0}{3}}}{a-\sqrt{\frac{2aa_0}{3}}}-1\right]=e18.13427 \tag{14.442}$$

The most convenient way to solve Eq. (14.442) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is

$$a=1.60061a_0=8.47006\ X\ 10^{-11}\ m \tag{14.443}$$

Substitution of Eq. (14.443) into Eq. (14.60) gives:

$$c'=1.03299a_0=5.46636\ X\ 10^{-11}\ m \tag{14.444}$$

The internuclear distance given by multiplying Eq. (14.444) by two is:

$$2c'=2.06598a_0=1.09327\ X\ 10^{-10}\ m \tag{14.445}$$

The experimental bond distance is [3]:

$$2c'=1.101\ X\ 10^{-10}\ m \tag{14.446}$$

Substitution of Eqs. (14.443-14.444) into Eq. (14.62) gives:

$$b=c=1.22265a_0=6.47000\ X\ 10^{-11}\ m \tag{14.447}$$

Substitution of Eqs. (14.443-14.444) into Eq. (14.63) gives:

$$e=0.64537 \tag{14.448}$$

The nucleus of the H atom and the nucleus of the C atom comprise the foci of each H_2-type ellipsoidal MO. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $C_{benzene}2sp^3$ HO are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where $r_n=r_{benzene2sp^3}=0.79597a_0$ is the radius of the $C_{benzene}2sp^3$ shell. Substitution of Eqs. (14.443-14.444) into Eq. (13.261) gives:

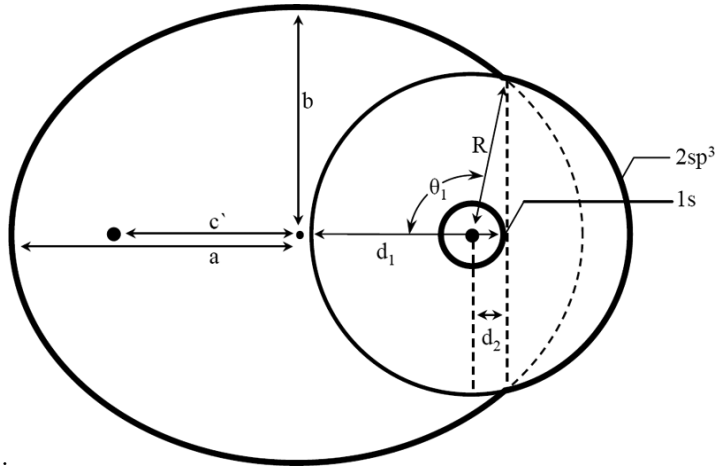
$$\theta'=74.42° \tag{14.449}$$

Then, the angle $\theta_{C-H_{benzene}2sp^3HO}$ the radial vector of the $C2sp^3$ HO makes with the internuclear axis is:

$$\theta_{C-H_{benzene}2sp^3HO}=180°-74.42°=105.58° \tag{14.450}$$

as shown in Figure 14.14.

Figure 14.14. The cross section of one $C-H$-bond MO of benzene showing the axes, angles, and point of intersection of the H_2-type ellipsoidal MO with the $C_{benzene}2sp^3$ HO. The continuation of the H_2-type-ellipsoidal-MO basis element beyond the intersection point with the $C_{benzene}2sp^3$ shell is shown as dashed since it only serves to solve the energy match with the $C_{benzene}2sp^3$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of the intersection point. The actual charge density is shown by the solid lines. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, $d_1:d_{C-H_{benzene},H_2MO}$, $\theta_1:\theta_{C-H_{benzene}2sp^3HO}$, $d_2:d_{C-H_{benzene}2sp^3HO}$, and $R:r_{benzene2sp^3}$



The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{C-H_{benzene},H_2MO}$ satisfies the following relationship:

$$r_{benzene\,2sp^3} \sin\theta_{C-H_{benzene}\,2sp^3HO} = 0.79597a_0 \sin\theta_{C-H_{benzene}\,2sp^3HO} = b\sin\theta_{C-H_{benzene},H_2MO} \tag{14.451}$$

such that

$$\theta_{C-H_{benzene},H_2MO} = \sin^{-1}\frac{0.79597a_0 \sin\theta_{C-H_{benzene}\,2sp^3HO}}{b} = \sin^{-1}\frac{0.79597a_0 \sin 105.58°}{b} \tag{14.452}$$

with the use of Eq. (14.450). Substitution of Eq. (14.447) into Eq. (14.452) gives:

$$\theta_{C-H_{benzene},H_2MO} = 38.84° \tag{14.453}$$

Then, the distance $d_{C-H_{benzene},H_2MO}$ along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$d_{C-H_{benzene},H_2MO} = a\cos\theta_{C-H_{benzene},H_2MO} \tag{14.454}$$

Substitution of Eqs. (14.443) and (14.453) into Eq. (14.454) gives:

$$d_{C-H_{benzene},H_2MO} = 1.24678a_0 = 6.59767\ X\ 10^{-11}\ m \tag{14.455}$$

The distance $d_{C-H_{benzene}\,2sp^3HO}$ along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals is given by:

$$d_{C-H_{benzene}\,2sp^3HO} = d_{C-H_{benzene},H_2MO} - c' \tag{14.456}$$

Substitution of Eqs. (14.444) and (14.455) into Eq. (14.456) gives:

$$d_{C-H_{benzene}\,2sp^3HO} = 0.21379a_0 = 1.13131\ X\ 10^{-11}\ m \tag{14.457}$$

The basis set of benzene, the ethylene molecule, is planar with bond angles of approximately 120° (Eqs. (14.298-14.302)). To form a closed ring of equivalent planar bonds, the $C=C$ bonds of benzene form a planar hexagon. The bond angle $\theta_{C=C=C}$ between the internuclear axis of any two adjacent $C=C$ bonds is:

$$\theta_{C=C=C} = 120° \tag{14.458}$$

The bond angle $\theta_{C=C-H}$ between the internuclear axis of each $C=C$ bond and the corresponding H atom of each CH group is

$$\theta_{C=C-H} = 120° \tag{14.459}$$

The experimental angle between the $C=C=C$ bonds is [13-15]:

$$\theta_{C=C=C} = 120° \tag{14.460}$$

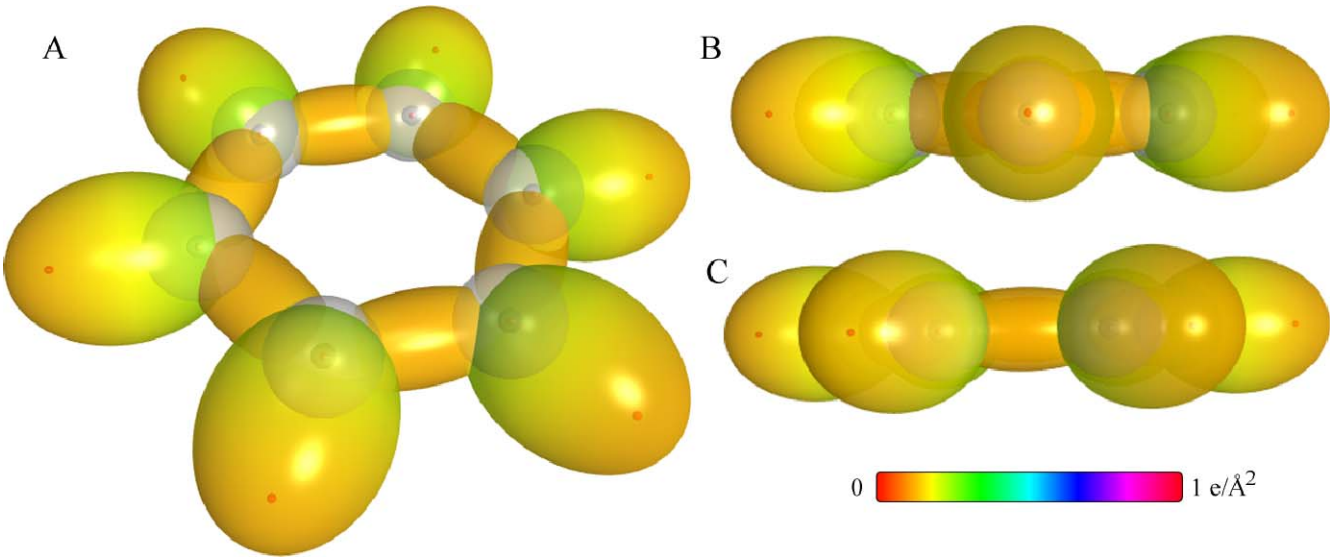
The experimental angle between the $C=C-H$ bonds is [13-15]:

$$\theta_{C=C-H} = 120° \tag{14.461}$$

The C_6H_6 MO shown in Figure 14.15 was rendered using these parameters.

The charge-density in the $C=C$-bond MO is increased by a factor of 0.25 per bond with the formation of the $C_{benzene}\,2sp^3$ HOs each having a smaller radius. Using the orbital composition of the CH groups (Eq. (14.439)) and the $C=C$-bond MO (Eq. (14.416)), the radii of $C1s = 0.17113a_0$ (Eq. (10.51)) and $C_{benzene}\,2sp^3 = 0.79597a_0$ (Eq. (14.520)) shells, and the parameters of the $C=C$-bond (Eqs. (13.3-13.4), (14.424-14.426), and (14.428-14.438)), the parameters of the $C-H$-bond MOs (Eqs. (13.3-13.4), (14.443-14.445), and (14.447-14.457)), and the bond-angle parameters (Eqs. (14.458-14.459)), the charge-density of the C_6H_6 MO comprising the linear combination of six sets of $C-H$-bond MOs with bridging $C\overset{3e}{=}C$-bond MOs is shown in Figure 14.15. Each $C-H$-bond MO comprises a H_2-type ellipsoidal MO and a $C_{benzene}\,2sp^3$ HO having the dimensional diagram shown in Figure 14.14. The $C=C$-bond MO comprises a H_2-type ellipsoidal MO bridging two sets of two $C_{benzene}\,2sp^3$ HOs having the dimensional diagram shown in Figure 14.13.

Figure 14.15. C_6H_6 MO comprising the linear combination of six sets of $C-H$ -bond MOs bridged by $C=C$ -bond MOs. (A) Color scale, translucent view of the charge-density of the C_6H_6 -bond MO with each $C_{benzene}2sp^3$ HOs shown transparently. Each $C=C$ -bond MO comprises a H_2 -type ellipsoidal MO bridging two pairs of $C_{benzene}2sp^3$ HOs. For each $C-H$ and $C=C$ bond, the ellipsoidal surface of the H_2 -type ellipsoidal MO that transitions to the $C_{benzene}2sp^3$ HO, the $C_{benzene}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown. (B)-(D) End-on view, translucent view high-lighting each $C=C$ -bond MO, and opaque view of the charge-density of the C_6H_6 MO, respectively.



ENERGIES OF THE *CH* GROUPS

The energies of each CH group of benzene are given by the substitution of the semiprincipal axes (Eqs. (14.443-14.444) and (14.447)) into the energy equations of hydrogen carbide (Eqs. (13.449-13.453)), with the exception that $E_T\left(C=C,2sp^3\right)$ (Eq. (14.247)) is subtracted from $E_T\left(CH\right)$ in Eq. (13.453).

$$V_e=\left(0.91771\right)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=-37.10024\ eV \tag{14.462}$$

$$V_p=\frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}=13.17125\ eV \tag{14.463}$$

$$T=\left(0.91771\right)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=11.58941\ eV \tag{14.464}$$

$$V_m=\left(0.91771\right)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=-5.79470\ eV \tag{14.465}$$

$$E_{T_{benzene}}\left(CH\right)=\begin{pmatrix}-\frac{e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]\\ -14.63489\ eV-\left(-1.13379\ eV\right)\end{pmatrix}=-31.63539\ eV \tag{14.466}$$

where $E_{T_{benzene}}\left(CH\right)$ is given by Eq. (14.440) which is reiteratively matched to Eq. (13.75) within five-significant-figure round off error.

The total energy of the $C-H$ -bond MO, $E_{T_{benzene}}\left(C-H\right)$, is given by the sum of $0.5E_T\left(C=C,2sp^3\right)$, the energy change of each $C2sp^3$ shell per single bond due to the decrease in radius with the formation of the corresponding $C=C$ -bond MO (Eq. (14.247)), and $E_{T_{benzene}}\left(CH\right)$, the σ MO contribution given by Eq. (14.441).

$$\begin{aligned} E_{T_{benzene}}(C-H) &= (0.5)E_T\left(C=C,2sp^3\right)+E_{T_{benzene}}(CH) \\ &= \left(\begin{array}{l}(0.5)(-1.13379\ eV)+ \\ \left(-\frac{e^2}{8\pi\varepsilon_0 c'}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]\right) \\ -14.63489\ eV-(-1.13379\ eV)\end{array}\right) \\ &= (0.5)(-1.13379\ eV)+(-31.63537\ eV) \\ &= -32.20226\ eV \end{aligned} \tag{14.467}$$

VIBRATION OF THE ^{12}CH GROUPS

The vibrational energy levels of CH in benzene may be solved using the methods given in the Vibration and Rotation of CH section.

THE DOPPLER ENERGY TERMS OF THE ^{12}CH GROUPS

The equations of the radiation reaction force of the CH groups in benzene are the same as those of the hydrogen carbide radical with the substitution of the CH -group parameters. Using Eq. (13.477), the angular frequency of the reentrant oscillation in the transition state is

$$\omega = \sqrt{\frac{0.75e^2}{4\pi\varepsilon_0 b^3}} = 2.64826\ X\ 10^{16}\ rad/s \tag{14.468}$$

where b is given by Eq. (14.447). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K = \hbar\omega = \hbar 2.64826\ X\ 10^{16}\ rad/s = 17.43132\ eV \tag{14.469}$$

In Eq. (11.181), substitution of $E_T(H_2)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each H_2-type MO, for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.469) for $\bar{E}_K$ gives the Doppler energy of the electrons for the reentrant orbit:

$$\bar{E}_D \cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}} = -31.63537\ eV\sqrt{\frac{2e(17.43132\ eV)}{m_e c^2}} = -0.26130\ eV \tag{14.470}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of CH due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (14.470) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of the $C-H$ bond. Using ω_e given by Eq. (13.458) for $\bar{E}_{Kvib}$ of the transition, $\bar{E}_{benzene\ osc}(^{12}CH)$ per bond is:

$$\bar{E}_{benzene\ osc}(^{12}CH) = \bar{E}_D + \bar{E}_{Kvib} = \bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{14.471}$$

$$\bar{E}_{benzene\ osc}(^{12}CH) = -0.26130\ eV + \frac{1}{2}(0.35532\ eV) = -0.08364\ eV \tag{14.472}$$

TOTAL AND BOND ENERGIES OF THE ^{12}CH GROUPS

$E_{benzeneT+osc}(^{12}CH)$, the total energy of each ^{12}CH group including the Doppler term, is given by the sum of $E_{T_{benzene}}(C-H)$ (Eq. (14.467)) and $\bar{E}_{benzene\ osc}(^{12}CH)$ given by Eq. (14.472).

$$\begin{aligned} E_{benzeneT+osc}(^{12}CH) &= \left(\begin{array}{l}\left(V_e+T+V_m+V_p+E\left(C,2sp^3\right)-E_T\left(C=C,2sp^3\right)\right) \\ +0.5E_T\left(C=C,2sp^3\right)+\bar{E}_{benzene\ osc}(^{12}CH)\end{array}\right) \\ &= E_{T_{benzene}}(C-H)+\bar{E}_{benzene\ osc}(^{12}CH) \end{aligned} \tag{14.473}$$

$$E_{benzeneT+osc}\left({}^{12}CH\right)=\left\{\begin{array}{l}\left(\begin{array}{l}\dfrac{-e^2}{8\pi\varepsilon_0 c'}\left[(0.91771)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+c'}{a-c'}-1\right]\\ -14.63489\ eV-(-1.13379\ eV)\end{array}\right)-0.5(1.13379\ eV)\\ -\left((31.63536831\ eV)\sqrt{\dfrac{2\hbar\sqrt{\dfrac{3}{4}\dfrac{e^2}{4\pi\varepsilon_0 b^3}}}{m_e c^2}}-\dfrac{1}{2}\hbar\sqrt{\dfrac{k}{\mu}}\right)\end{array}\right\}$$
$$=-32.20226\ eV-\left(0.26130\ eV-\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \tag{14.474}$$

From Eqs. (14.472-14.474), the total energy of each ${}^{12}CH$ is:

$$\begin{aligned}E_{benzeneT+osc}\left({}^{12}CH\right)&=-32.20226\ eV+\bar{E}_{benzene\ osc}\left({}^{12}CH_2\right)\\&=-32.20226\ eV-\left(0.26130\ eV-\frac{1}{2}(0.35532\ eV)\right)\\&=-32.28590\ eV\end{aligned} \tag{14.475}$$

where ω_e given by Eq. (13.458) was used for the $\hbar\sqrt{\dfrac{k}{\mu}}$ term.

As in the case of ${}^{12}CH_2$, ${}^{14}NH$, and acetylene, the dissociation of the $C=C$ bonds forms three unpaired electrons per central atom wherein the magnetic moments cannot all cancel. The energy per atom $E(magnetic)$ is given by Eq. (13.524). Thus, the bond dissociation energy of each CH group of the linear combination to form benzene, $E_{D_{benzene}}\left({}^{12}CH\right)$, is given by the sum of the total energies of the $C2sp^3$ HO and the hydrogen atom minus the sum of $E_{benzeneT+osc}\left({}^{12}CH\right)$ and $E(magnetic)$ given by Eq. (13.524):

$$E_{D_{benzene}}\left({}^{12}CH\right)=E\left(C,2sp^3\right)+E(H)-\left(E_{benzeneT+osc}\left({}^{12}CH\right)+E(magnetic)\right) \tag{14.476}$$

$E\left(C,2sp^3\right)$ is given by Eq. (13.428), $E_D(H)$ is given by Eq. (13.154), and $E(magnetic)$ is given by Eq. (13.524). Thus, $E_{D_{benzene}}\left({}^{12}CH\right)$ given by Eqs. (13.154), (13.428), (13.524), (14.475), and (14.476) is:

$$\begin{aligned}E_{D_{benzene}}\left({}^{12}CH\right)&=-(14.63489\ eV+13.59844\ eV)-\left(E_{benzeneT+osc}(CH)+E(magnetic)\right)\\&=-28.23333\ eV-(-32.28590\ eV+0.14803\ eV)\\&=3.90454\ eV\end{aligned} \tag{14.477}$$

SUM OF THE ENERGIES OF THE $C=C$ σ MO ELEMENT AND THE HOs OF BENZENE

The energy components of V_e, V_p, T, V_m, and E_T of the $C=C$-bond MO of benzene are the same as those of the CH_2CH_2 MO except that the hybridization factor is given by Eq. (14.417). The energies of each $C=C$-bond MO are given by the substitution of the semiprincipal axes (Eqs. (14.424-14.425) and (14.428)) into energy equations of the CH_2CH_2 MO (Eqs. (14.319-14.323)), with the exception that the hybridization factor is 0.85252 (Eq. (14.417)).

$$V_e=2(0.85252)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=-101.12679\ eV \tag{14.478}$$

$$V_p=2\frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}=20.69825\ eV \tag{14.479}$$

$$T=2(0.85252)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=34.31559\ eV \tag{14.480}$$

$$V_m=2(0.85252)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}=-17.15779\ eV \tag{14.481}$$

$$E_T(C=C,\sigma)=-\frac{2e^2}{8\pi\varepsilon_0 c'}\left[(0.85252)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]=-63.27075\ eV \tag{14.482}$$

where $E_T\left(C=C,\sigma\right)$ is the total energy of the $C=C$ σ MO given by Eq. (14.421) which is reiteratively matched to two times Eq. (13.75) within five-significant-figure round off error.

The total energy of the $C=C$-bond MO, $E_T\left(C=C\right)$, is given by the sum of two times $E_T\left(C=C,2sp^3\right)$, the energy change of each $C2sp^3$ shell due to the decrease in radius with the formation of the $C=C$-bond MO (Eq. (14.247)), and $E_T\left(C=C,\sigma\right)$, the σ MO contribution given by Eq. (14.422).

$$\begin{aligned} E_T\left(C=C\right) &= 2E_T\left(C=C,2sp^3\right)+E_T\left(C=C,\sigma\right) \\ &= \left(\begin{array}{l} 2(-1.13380\ eV)+ \\ \left(-\dfrac{2e^2}{8\pi\varepsilon_0 c'}\left[(0.85252)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+c'}{a-c'}-1\right]\right) \end{array}\right) \\ &= 2(-1.13380\ eV)+(-63.27074\ eV)=-65.53833\ eV \end{aligned} \tag{14.483}$$

which is the same $E_T\left(C=C,\sigma\right)$ of ethylene given by Eq. (14.324).

VIBRATION OF BENZENE

The $C=C$ vibrational energy levels of C_6H_6 may be solved as six sets of equivalent coupled harmonic oscillators where each C is further coupled to the corresponding $C-H$ oscillator by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

THE DOPPLER ENERGY TERMS OF THE $C=C$-BOND MO ELEMENT OF BENZENE

The equations of the radiation reaction force of the $C=C$-bond MO of benzene are given by Eq. (13.142), except the force-constant factor is $\left(0.85252\right)0.5$ based on the force constant k' of Eq. (14.418), and the $C=C$-bond MO parameters are used. The angular frequency of the reentrant oscillation in the transition state is:

$$\omega=\sqrt{\frac{0.85252\dfrac{(0.5)e^2}{4\pi\varepsilon_0 b^3}}{m_e}}=4.97272\ X\ 10^{16}\ rad/s \tag{14.484}$$

where b is given by Eq. (14.428). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K=\hbar\omega=\hbar 4.97272\ X\ 10^{16}\ rad/s=32.73133\ eV \tag{14.485}$$

In Eq. (11.181), substitution of $E_T\left(H_2\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each H_2-type MO, for E_{hv}, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.485) for $\bar{E}_K$ gives the Doppler energy of the electrons for the reentrant orbit:

$$\bar{E}_D\cong E_{hv}\sqrt{\frac{2\bar{E}_K}{Mc^2}}=-31.63536831\ eV\sqrt{\frac{2e\left(32.73133\ eV\right)}{m_e c^2}}=-0.35806\ eV \tag{14.486}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of the $C=C$-bond MO due to the reentrant orbit of the bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (14.486) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of the $C=C$ bond. Using the experimental $C=C$ $E_{vib}\left(\upsilon_{16}\right)$ of 1584.8 cm^{-1} $\left(0.19649\ eV\right)$ [16] for $\bar{E}_{Kvib}$ of the transition state having two bonds, $\bar{E}'_{osc}\left(C=C,\sigma\right)$ per bond is:

$$\bar{E}'_{osc}\left(C=C,\sigma\right)=\bar{E}_D+\bar{E}_{Kvib}=\bar{E}_D+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{14.487}$$

$$\bar{E}'_{osc}\left(C=C,\sigma\right)=-0.35806\ eV+\frac{1}{2}\left(0.19649\ eV\right)=-0.25982\ eV \tag{14.488}$$

Given that the vibration and reentrant oscillation is for two $C-C$ bonds of each $C=C$ double bond, $\bar{E}_{benzene\ osc}\left(C=C,\sigma\right)$, is:

$$\bar{E}_{benzene\ osc}\left(C=C,\sigma\right)=2\left(\bar{E}_D+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)=2\left(-0.35806\ eV+\frac{1}{2}\left(0.19649\ eV\right)\right)=-0.51963\ eV \tag{14.489}$$

TOTAL ENERGIES OF THE $C=C$-BOND MO ELEMENT OF BENZENE

$E_{T+osc}(C=C)$, the total energy of the $C=C$-bond MO of benzene including the Doppler term, is given by the sum of $E_T(C=C)$ (Eq. (14.483)) and $\bar{E}_{benzene\ osc}(C=C,\sigma)$ given by Eq. (14.489).

$$\begin{aligned} E_{T+osc}(C=C) &= V_e + T + V_m + V_p + 2E_T\left(C=C,2sp^3\right) + \bar{E}_{benzene\ osc}(C=C,\sigma) \\ &= E_T(C=C,\sigma) + 2E_T\left(C=C,2sp^3\right) + \bar{E}_{benzene\ osc}(C=C,\sigma) \\ &= E_T(C=C) + \bar{E}_{benzene\ osc}(C=C,\sigma) \end{aligned} \tag{14.490}$$

$$\begin{aligned} E_{T+osc}(C=C) &= \left\{ \begin{array}{l} \left(\dfrac{-2e^2}{8\pi\varepsilon_0 c'} \left[(0.85252)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+c'}{a-c'} - 1 \right] + 2E_T\left(C=C,2sp^3\right) \right) \\ -2\left((31.63536831\ eV)\sqrt{\dfrac{2\hbar\sqrt{\dfrac{(0.85252)\dfrac{1}{2}\dfrac{e^2}{4\pi\varepsilon_0 b^3}}{m_e}}}{m_e c^2}} - \dfrac{1}{2}\hbar\sqrt{\dfrac{k}{\mu}} \right) \end{array} \right\} \\ &= -65.53833\ eV - 2\left(0.35806\ eV - \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \right) \end{aligned} \tag{14.491}$$

From Eqs. (14.489-14.491), the total energy of the $C=C$-bond MO is:

$$\begin{aligned} E_{T+osc}(C=C) &= -63.27074\ eV + 2E_T\left(C=C,2sp^3\right) + \bar{E}_{benzene\ osc}(C=C,\sigma) \\ &= -63.27074\ eV + 2(-1.13380\ eV) - 2\left(0.35806\ eV - \frac{1}{2}(0.19649\ eV) \right) \\ &= -66.05796\ eV \end{aligned} \tag{14.492}$$

where the experimental E_{vib} was used for the $\hbar\sqrt{\dfrac{k}{\mu}}$ term.

TOTAL BOND DISSOCIATION ENERGY OF BENZENE

Ethylene serves as a basis element for the $C=C$ bonding of benzene wherein each of the six $C\overset{3e}{=}C$ bonds of benzene comprises $(0.75)(4)=3$ electrons according to Eq. (14.416). The total energy of the bonds of the eighteen electrons of the $C\overset{3e}{=}C$ bonds of benzene, $E_T\left(C_6H_6,C\overset{3e}{=}C\right)$, is given by $(6)(0.75)$ times $E_{T+osc}(C=C)$ (Eq. (14.492)), the total energy of the $C=C$-bond MO of benzene including the Doppler term, minus eighteen times $E\left(C,2sp^3\right)$ (Eq. (14.146)), the initial energy of each $C2sp^3$ HO of each C that forms the double $C=C$ bonds. Thus, the total energy of the six $C\overset{3e}{=}C$ bonds of benzene is:

$$\begin{aligned} E_T\left(C_6H_6,C\overset{3e}{=}C\right) &= (6)(0.75)E_{T+osc}(C=C) - 18E\left(C,2sp^3\right) \\ &= (6)(0.75)(-66.05796\ eV) - 18(-14.63489\ eV) \\ &= -297.26081\ eV - (-263.42798\ eV) \\ &= -33.83284\ eV \end{aligned} \tag{14.493}$$

Each of the $C-H$ bonds of benzene comprises two electrons according to Eq. (14.439). From the energy of each $C-H$ bond, $-E_{D_{benzene}}\left({}^{12}CH\right)$ (Eq. (14.477)), the total energy of the twelve electrons of the six $C-H$ bonds of benzene, $E_T\left(C_6H_6,C-H\right)$, is given by:

$$E_T\left(C_6H_6,C-H\right) = (6)\left(-E_{D_{benzene}}\left({}^{12}CH\right)\right) = 6(-3.90454\ eV) = -23.42724\ eV \tag{14.494}$$

The total bond dissociation energy of benzene, $E_D\left(C_6H_6\right)$, is given by the negative sum of $E_T\left(C_6H_6,C\overset{3e}{=}C\right)$ (Eq. (14.493)) and $E_T\left(C_6H_6,C-H\right)$ (Eq. (14.494)):

$$\begin{aligned} E_D\left(C_6H_6\right) &= -\left(E_T\left(C_6H_6,C\overset{3e}{=}C\right) + E_T\left(C_6H_6,C-H\right) \right) \\ &= -\left((-33.83284\ eV) + (-23.42724\ eV) \right) = 57.2601\ eV \end{aligned} \tag{14.495}$$

The experimental total bond dissociation energy of benzene, $E_T\left(C_6H_6\right)$, is given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(benzene\left(gas\right)\right)$) and the sum of the enthalpy of the formation of the gaseous carbons ($\Delta H_f\left(C\left(gas\right)\right)$) and hydrogen ($\Delta H_f\left(H\left(gas\right)\right)$) atoms. The heats of formation are [17-18]:

$$\Delta H_f\left(benzene\left(gas\right)\right)=82.9\ kJ/mole\ \left(0.8592\ eV/molecule\right) \tag{14.496}$$

$$\Delta H_f\left(C\left(gas\right)\right)=716.68\ kJ/mole\ \left(7.42774\ eV/atom\right) \tag{14.497}$$

$$\Delta H_f\left(H\left(gas\right)\right)=217.998\ kJ/mole\ \left(2.259353\ eV/atom\right) \tag{14.498}$$

thus, the total bond dissociation energy of benzene, $E_D\left(C_6H_6\right)$, is:

$$\begin{aligned} E_D\left(C_6H_6\right)-E_T\left(C_6H_6\right) &= -\left(\Delta H_f\left(benzene\left(gas\right)\right)-\left(6\Delta H_f\left(C\left(gas\right)\right)+6\Delta H_f\left(H\left(gas\right)\right)\right)\right) \\ &= -\left(0.8592\ eV-6\left(7.42774\ eV+2.259353\ eV\right)\right) \\ &= 57.26\ eV \end{aligned} \tag{14.499}$$

where $E_T\left(C_6H_6\right)$ is the total energy of the bonds. The results of the determination of bond parameters of C_6H_6 are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

CONTINUOUS-CHAIN ALKANES ($C_nH_{2n+2},\ n=3,4,5...\infty$)

The continuous chain alkanes, C_nH_{2n+2}, are the homologous series comprising terminal methyl groups at each end of the chain with $n-2$ methylene (CH_2) groups in between:

$$CH_3\left(CH_2\right)_{n-2}CH_3 \tag{14.500}$$

C_nH_{2n+2} can be solved using the same principles as those used to solve ethane and ethylene wherein the $2s$ and $2p$ shells of each C hybridize to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. Three H AOs combine with three carbon $2sp^3$ HOs and two H AOs combine with two carbon $2sp^3$ HOs to form each methyl and methylene group, respectively, where each bond comprises a H_2-type MO developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section. The CH_3 and CH_2 groups bond by forming H_2-type MOs between the remaining $C2sp^3$ HOs on the carbons such that each carbon forms four bonds involving its four $C2sp^3$ HOs.

FORCE BALANCE OF THE $C-C$-BOND MOs OF CONTINUOUS-CHAIN ALKANES

C_nH_{2n+2} comprises a chemical bond between two terminal CH_3 radicals and $n-2$ CH_2 radicals wherein each methyl and methylene radical comprises three and two chemical bonds, respectively, between carbon and hydrogen atoms. The solution of the parameters of CH_3 is given in the Methyl Radical (CH_3) section. The solution of the parameters of CH_2 is given in the Dihydrogen Carbide Radical (CH_2) section and follows the same procedure. Each $C-H$ bond having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of 75% H_2-type ellipsoidal MO and 25% $C2sp^3$ HO as given by Eq. (13.429):

$$1\ C2sp^3+0.75\ H_2\ MO\rightarrow C-H\ MO \tag{14.501}$$

The proton of the H atom and the nucleus of the C atom are along each internuclear axis and serve as the foci. As in the case of H_2, each of the $C-H$-bond MOs is a prolate spheroid with the exception that the ellipsoidal MO surface cannot extend into $C2sp^3$ HO for distances shorter than the radius of the $C2sp^3$ shell since it is energetically unfavorable. Thus, each MO surface comprises a prolate spheroid at the H proton that is continuous with the $C2sp^3$ shell at the C atom whose nucleus serves as the other focus. The electron configuration and the energy, $E\left(C,2sp^3\right)$, of the $C2sp^3$ shell is given by Eqs. (13.422) and (13.428), respectively. The central paramagnetic force due to spin of each $C-H$ bond is provided by the spin-pairing force of the CH_3 or CH_2 MO that has the symmetry of an s orbital that superimposes with the $C2sp^3$ orbitals such that the corresponding angular momenta are unchanged. The energies of each CH_3 and CH_2 MO involve each $C2sp^3$ and each $H1s$ electron with the formation of each $C-H$ bond. The sum of the energies of the H_2-type ellipsoidal MOs is matched to that of the $C2sp^3$ shell.

The force balance of the $C-H$-bond MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.139) and the energy matching condition between the $C2sp^3$-HO components of the MO.

The CH_3 and CH_2 groups form $C-C$ bonds comprising H_2-type MOs between the remaining $C2sp^3$ HOs on the carbons such that each carbon forms four bonds involving its four $C2sp^3$ HOs. The sharing of electrons between any two $C2sp^3$ HOs to form a molecular orbital (MO) comprising two spin-paired electrons permits each $C2sp^3$ HO to decrease in radius and energy. As in the case of the $C-H$ bonds, each $C-C$-bond MO is a prolate-spheroidal-MO surface that cannot extend into $C2sp^3$ HO for distances shorter than the radius of the $C2sp^3$ shell of each atom. Thus, the MO surface comprises a partial prolate spheroid in between the carbon nuclei and is continuous with the $C2sp^3$ shell at each C atom. The energy of the H_2-type ellipsoidal MO is matched to that of the $C2sp^3$ shell. As in the case of previous examples of energy-matched MOs such as the $C-C$-bond MO of ethane, each $C-C$-bond MO of C_nH_{2n+2} must comprise 75% of a H_2-type ellipsoidal MO in order to match potential, kinetic, and orbital energy relationships. Thus, the $C-C$-bond MO must comprise two $C2sp^3$ HOs and 75% of a H_2-type ellipsoidal MO divided between the two $C2sp^3$ HOs:

$$2\ C2sp^3 + 0.75\ H_2\ MO \rightarrow C-C-bond\ MO \tag{14.502}$$

The linear combination of the H_2-type ellipsoidal MO with each $C2sp^3$ HO further comprises an excess 25% charge-density contribution from each $C2sp^3$ HO to the $C-C$-bond MO to achieve an energy minimum. The force balance of the $C-C$-bond MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.502) and the energy matching condition between the $C2sp^3$-HO components of the MO.

Before bonding, the $2sp^3$ hybridized orbital arrangement of each carbon atom is given by Eq. (14.140). The sum $E_T\left(C,2sp^3\right)$ of calculated energies of C, C^+, C^{2+}, and C^{3+} is given by Eq. (14.141). The radius r_{2sp^3} of the $C2sp^3$ shell is given by Eq. (14.142). The Coulombic energy $E_{Coulomb}\left(C,2sp^3\right)$ and the energy $E\left(C,2sp^3\right)$ of the outer electron of the $C2sp^3$ shell are given by Eqs. (14.143) and (14.146), respectively.

The formation of each $C-C$ bond of C_nH_{2n+2} further requires that the energy of all H_2-type prolate spheroidal MOs (σ MOs) be matched at all $C2sp^3$ HOs since they are continuous throughout the molecule. Thus, the energy of each $C2sp^3$ HO must be a linear combination of that of the CH_3 and CH_2 groups that serve as basis elements. Each CH_3 forms one $C-C$ bond, and each CH_2 group forms two. Thus, the energy of each $C2sp^3$ HO of each CH_3 and CH_2 group alone is given by that in ethane and ethylene, respectively. The parameters of ethane and ethylene are given by Eqs. (14.147-14.151) and (14.244-14.247), respectively. The alkane parameters can be determined by first reviewing those of ethane and ethylene.

With the formation of the $C-C$-bond MO of ethane from two methyl radicals, each having a $C2sp^3$ electron with an energy given by Eq. (14.146), the total energy of the state is given by the sum over the four electrons. The sum $E_T\left(C_{ethane},2sp^3\right)$ of calculated energies of $C2sp^3$, C^+, C^{2+}, and C^{3+} given by Eq. (14.147), is:

$$\begin{aligned} E_T\left(C_{ethane},2sp^3\right) &= -\left(64.3921\ eV + 48.3125\ eV + 24.2762\ eV + E\left(C,2sp^3\right)\right) \\ &= -\left(64.3921\ eV + 48.3125\ eV + 24.2762\ eV + 14.63489\ eV\right) \\ &= -151.61569\ eV \end{aligned} \tag{14.503}$$

where $E\left(C,2sp^3\right)$ is the sum of the energy of C, $-11.27671\ eV$, and the hybridization energy. The orbital-angular-momentum interactions also cancel such that the energy of the $E_T\left(C_{ethane},2sp^3\right)$ is purely Coulombic.

The sharing of electrons between two $C2sp^3$ HOs to form a $C-C$-bond MO permits each participating hybridized orbital to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each $C2sp^3$ HO donates an excess of 25% of its electron density to the $C-C$-bond MO to form an energy minimum. By considering this electron redistribution in the ethane molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{ethane\,2sp^3}$ of the $C2sp^3$ shell of ethane may be calculated from the Coulombic energy using Eq. (10.102).

$$r_{ethane\,2sp^3} = \left(\sum_{n=2}^{5}(Z-n) - 0.25\right)\frac{e^2}{8\pi\varepsilon_0\left(e151.61569\ eV\right)} = \frac{9.75e^2}{8\pi\varepsilon_0\left(e151.61569\ eV\right)} = 0.87495a_0 \tag{14.504}$$

using Eqs. (10.102) and (14.504), the Coulombic energy $E_{Coulomb}\left(C_{ethane},2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is:

$$E_{Coulomb}\left(C_{ethane},2sp^3\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{ethane\,2sp^3}} = \frac{-e^2}{8\pi\varepsilon_0 0.87495a_0} = -15.55033\ eV \tag{14.505}$$

During hybridization, one of the spin-paired $2s$ electrons is promoted to the $C2sp^3$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (14.145). Using Eqs. (14.145) and (14.505), the energy $E\left(C_{ethane},2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is:

$$E\left(C_{ethane},2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{ethane\,2sp^3}}+\frac{2\pi\mu_0 e^2\hbar^2}{m_e^2\left(r_3\right)^3}=-15.55033\ eV+0.19086\ eV=-15.35946\ eV \tag{14.506}$$

thus, $E_T\left(C-C,2sp^3\right)$, the energy change of each $C2sp^3$ shell with the formation of the $C-C$-bond MO is given by the difference between Eq. (14.146) and Eq. (14.506).

$$E_T\left(C-C,2sp^3\right)=E\left(C_{ethane},2sp^3\right)-E\left(C,2sp^3\right)=-15.35946\ eV-\left(-14.63489\ eV\right)=-0.72457\ eV \tag{14.507}$$

Next, consider the formation of the $C=C$-bond MO of ethylene from two CH_2 radicals, each having a $C2sp^3$ electron with an energy given by Eq. (14.146). The sum $E_T\left(C_{ethylene},2sp^3\right)$ of calculated energies of $C2sp^3$, C^+, C^{2+}, and C^{3+} is given by Eq. (14.147). The sharing of electrons between two pairs of $C2sp^3$ HOs to form a $C=C$-bond MO permits each participating HO to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each participating $C2sp^3$ HO donates an excess of 25% of its electron density to the $C=C$-bond MO to form an energy minimum. By considering this electron redistribution in the ethylene molecule as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius $r_{ethylene\,2sp^3}$ of the $C2sp^3$ shell of ethylene may be calculated from the Coulombic energy using Eqs. (10.102) and (14.147):

$$\begin{aligned} r_{ethylene\,2sp^3} &= \left(\sum_{n=2}^{5}(Z-n)-0.5\right)\frac{e^2}{8\pi\varepsilon_0\left(e151.61569\ eV\right)} \\ &= \frac{9.5e^2}{8\pi\varepsilon_0\left(e151.61569\ eV\right)} \\ &= 0.85252a_0 \end{aligned} \tag{14.508}$$

where $Z=6$ for carbon. Using Eqs. (10.102) and (14.508), the Coulombic energy $E_{Coulomb}\left(C_{ethylene},2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is:

$$E_{Coulomb}\left(C_{ethylene},2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{ethylene\,2sp^3}}=\frac{-e^2}{8\pi\varepsilon_0 0.85252a_0}=-15.95955\ eV \tag{14.509}$$

During hybridization, one of the spin-paired $2s$ electrons is promoted to the $C2sp^3$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (14.145). Using Eqs. (14.145) and (14.509), the energy $E\left(C_{ethylene},2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is:

$$E\left(C_{ethylene},2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{ethylene\,2sp^3}}+\frac{2\pi\mu_0 e^2\hbar^2}{m_e^2\left(r_3\right)^3}=-15.95955\ eV+0.19086\ eV=-15.76868\ eV \tag{14.510}$$

thus, $E_T\left(C=C,2sp^3\right)$, the energy change of each $C2sp^3$ shell with the formation of the $C=C$-bond MO is given by the difference between Eq. (14.146) and Eq. (14.510):

$$\begin{aligned} E_T\left(C=C,2sp^3\right) &= E\left(C_{ethylene},2sp^3\right)-E\left(C,2sp^3\right) \\ &= -15.76868\ eV-\left(-14.63489\ eV\right) \\ &= -1.13380\ eV \end{aligned} \tag{14.511}$$

To meet the energy matching condition for all σ MOs at all $C2sp^3$ HOs, the energy $E\left(C_{alkane},2sp^3\right)$ of the outer electron of the $C2sp^3$ shell of each alkane carbon atom must be the average of $E\left(C_{ethane},2sp^3\right)$ (Eq. (14.506)) and $E\left(C_{ethylene},2sp^3\right)$ (Eq. (14.510)).

$$\begin{aligned} E\left(C_{alkane},2sp^3\right) &= \frac{E\left(C_{ethane},2sp^3\right)+E\left(C_{ethylene},2sp^3\right)}{2} \\ &= \frac{\left(-15.35946\ eV\right)+\left(-15.76868\ eV\right)}{2} \\ &= -15.56407\ eV \end{aligned} \tag{14.512}$$

And, $E_{T_{alkane}}\left(C-C,2sp^3\right)$, the energy change of each $C2sp^3$ shell with the formation of each $C-C$-bond MO, must be the average of $E_T\left(C-C,2sp^3\right)$ (Eq. (14.507)) and $E_T\left(C=C,2sp^3\right)$ (Eq. (14.511)).

$$\begin{aligned} E_{T_{alkane}}\left(C-C,2sp^3\right) &= \frac{E_T\left(C-C,2sp^3\right)+E_T\left(C=C,2sp^3\right)}{2} \\ &= \frac{\left(-0.72457\ eV\right)+\left(-1.13379\ eV\right)}{2} \\ &= -0.92918\ eV \end{aligned} \tag{14.513}$$

using Eq. (10.102), the radius $r_{alkane2sp^3}$ of the $C2sp^3$ shell of each carbon atom of C_nH_{2n+2} may be calculated from the Coulombic energy using the initial energy $E_{Coulomb}\left(C,2sp^3\right)=-14.82575\ eV$ (Eq. (14.143)) and $E_{T_{alkane}}\left(C-C,2sp^3\right)$ Eq. (14.513)), the energy change of each $C2sp^3$ shell with the formation of each $C-C$-bond MO. Consider the case of a methyl carbon which donates $E_{T_{alkane}}\left(C-C,2sp^3\right)$ Eq. (14.513)) to a single $C-C$ bond:

$$\begin{aligned} r_{alkane2sp^3} &= \frac{-e^2}{8\pi\varepsilon_0\left(E_{Coulomb}\left(C,2sp^3\right)+E_{T_{alkane}}\left(C-C,2sp^3\right)\right)} \\ &= \frac{e^2}{8\pi\varepsilon_0\left(e14.825751\ eV+e0.92918\ eV\right)} \\ &= 0.86359a_0 \end{aligned} \tag{14.514}$$

using Eqs. (10.102) and (14.514), the Coulombic energy $E_{Coulomb}\left(C_{alkane},2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is:

$$E_{Coulomb}\left(C_{alkane},2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{alkane2sp^3}}=\frac{-e^2}{8\pi\varepsilon_0 0.86359a_0}=-15.75493\ eV \tag{14.515}$$

During hybridization, one of the spin-paired $2s$ electrons is promoted to the $C2sp^3$ shell as an unpaired electron. The energy for the promotion is the magnetic energy given by Eq. (14.145). Using Eqs. (14.145) and (14.515), the energy $E\left(C_{alkane},2sp^3\right)$ of the outer electron of the $C2sp^3$ shell is:

$$E\left(C_{alkane},2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{alkane2sp^3}}+\frac{2\pi\mu_0 e^2\hbar^2}{m_e^2\left(r_3\right)^3}=-15.75493\ eV+0.19086\ eV=-15.56407\ eV \tag{14.516}$$

thus, $E_{T_{alkane}}\left(C-C,2sp^3\right)$, the energy change of each $C2sp^3$ shell with the formation of each $C-C$-bond MO is given by the difference between Eq. (14.146) and Eq. (14.516):

$$E_{T_{alkane}}\left(C-C,2sp^3\right)=E\left(C_{alkane},2sp^3\right)-E\left(C,2sp^3\right)=-15.56407\ eV-\left(-14.63489\ eV\right)=-0.92918\ eV \tag{14.517}$$

which agrees with Eq. (14.513).

The energy contribution due to the charge donation at each carbon superimposes linearly. In general, the radius r_{mol2sp^3} of the $C2sp^3$ HO of a carbon atom of a group of a given molecule is calculated using Eq. (14.514) by considering $\sum E_{T_{mol}}\left(MO,2sp^3\right)$, the total energy donation to each bond with which it participates in bonding. The general equation for the radius is given by:

$$\begin{aligned} r_{mol2sp^3} &= \frac{-e^2}{8\pi\varepsilon_0\left(E_{Coulomb}\left(C,2sp^3\right)+\sum E_{T_{mol}}\left(MO,2sp^3\right)\right)} \\ &= \frac{e^2}{8\pi\varepsilon_0\left(e14.825751\ eV+\sum\left|E_{T_{mol}}\left(MO,2sp^3\right)\right|\right)} \end{aligned} \tag{14.518}$$

The $C2sp^3$ HO of each methyl group of an alkane contributes $-0.92918\ eV$ to the corresponding single $C-C$ bond; thus, the corresponding $C2sp^3$ HO radius is given by Eq. (14.514). The $C2sp^3$ HO of each methylene group of C_nH_{2n+2} contributes $-0.92918\ eV$ to each of the two corresponding $C-C$ bond MOs. Thus, the radius of each methylene group of an alkane is given by:

$$r_{alkaneC_{methylene}2sp^3} = \frac{-e^2}{8\pi\varepsilon_0\left(E_{Coulomb}\left(C,2sp^3\right)+\sum E_{T_{alkane}}\left(methylene\ C-C,2sp^3\right)\right)}$$
$$= \frac{e^2}{8\pi\varepsilon_0\left(e14.825751\ eV + e0.92918\ eV + e0.92918\ eV\right)} \tag{14.519}$$
$$= 0.81549a_0$$

As in the case with ethane, the H_2-type ellipsoidal MO comprises 75% of the $C-C$-bond MO shared between two $C2sp^3$ HOs corresponding to the electron charge density in Eq. (11.65) of $\frac{-0.75e}{2}$. But, the additional 25% charge-density contribution to the $C-C$-bond MO causes the electron charge density in Eq. (11.65) to be $\frac{-e}{2} = -0.5e$. Thus, the force constant k' to determine the ellipsoidal parameter c' in terms of the central force of the foci is given by Eq. (14.152). The distance from the origin of the $C-C$-bond MO to each focus c' is given by Eq. (14.153). The internuclear distance from is given by Eq. (14.154). The length of the semiminor axis of the prolate spheroidal $C-C$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of the $C-C$-bond MO. Since the $C-C$-bond MO comprises a H_2-type-ellipsoidal MO that transitions to the $C_{alkane}2sp^3$ HO of each carbon, the energy $E\left(C_{alkane},2sp^3\right)$ in Eq. (14.512) adds to that of the H_2-type ellipsoidal MO to give the total energy of the $C-C$-bond MO. From the energy equation and the relationship between the axes, the dimensions of the $C-C$-bond MO are solved. Similarly, $E\left(C_{alkane},2sp^3\right)$ is added to the energy of the H_2-type ellipsoidal MO of each $C-H$ bond of the methyl and methylene groups to give their total energy. From the energy equation and the relationship between the axes, the dimensions of the equivalent $C-H$-bond MOs of the methyl and methylene groups in the alkane are solved.

The general equations for the energy components of V_e, V_p, T, V_m, and E_T of each $C-C$-bond MO are the same as those of the CH MO except that energy of the $C_{alkane}2sp^3$ HO is used. The energy components at each carbon atom superimpose linearly and may be treated independently. Since each prolate spheroidal H_2-type MO transitions to the $C_{alkane}2sp^3$ HO of each corresponding carbon of the bond and the energy of the $C_{alkane}2sp^3$ shell treated independently must remain constant and equal to the $E\left(C_{alkane},2sp^3\right)$ given by Eq. (14.512), the total energy $E'_{T_{alkane}}\left(C-C,\sigma\right)$ of the σ component of each $C-C$-bond MO is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $C_{alkane}2sp^3$ HO and the H_2-type ellipsoidal MO that forms the σ component of the $C-C$-bond MO as given by Eq. (14.502) with the electron charge redistribution. The total number of $C-C$ bonds in C_nH_{2n+2} is $n-1$. Using Eqs. (13.431) and (14.512), $E_{T_{alkane}}\left(C-C,\sigma\right)$ of the $n-1$ bonds is given by:

$$E_{T_{alkane}}\left(C-C,\sigma\right) = \left(n-1\right)\left(E_T + E\left(C_{alkane},2sp^3\right)\right)$$
$$= \left(n-1\right)\left(-\frac{e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-15.56407\ eV\right) \tag{14.520}$$

To match the boundary condition that the total energy of each H_2-type ellipsoidal MO is given by Eqs. (11.212) and (13.75), $E_{T_{alkane}}\left(C-C,\sigma\right)$ given by Eq. (14.520) is set equal to $\left(n-1\right)$ times Eq. (13.75).

$$E_{T_{alkane}}\left(C-C,\sigma\right) = \left(n-1\right)\left(\begin{array}{l}-\frac{e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]\\ -15.56407\ eV\end{array}\right) = \left(n-1\right)\left(-31.63536831\ eV\right) \tag{14.521}$$

From the energy relationship given by Eq. (14.521) and the relationship between the axes given by Eqs. (14.153-14.154) and (13.62-13.63), the dimensions of the $C-C$-bond MO can be solved.

Substitution of Eq. (14.153) into Eq. (14.521) gives:

$$\frac{e^2}{8\pi\varepsilon_0\sqrt{aa_0}}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{aa_0}}{a-\sqrt{aa_0}}-1\right] = e16.07130 \tag{14.522}$$

The most convenient way to solve Eq. (14.522) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a = 2.12499a_0 = 1.12450\ X\ 10^{-10}\ m \tag{14.523}$$

Substitution of Eq. (14.523) into Eq. (14.155) gives:

$$c' = 1.45774a_0 = 7.71400\ X\ 10^{-11}\ m \tag{14.524}$$

The internuclear distance given by multiplying Eq. (14.524) by two is:

$$2c' = 2.91547a_0 = 1.54280\ X\ 10^{-10}\ m \tag{14.525}$$

The experimental $C-C$ bond distance of propane is [3]:

$$2c' = 1.532\ X\ 10^{-10}\ m \tag{14.526}$$

The experimental $C-C$ bond distance of butane is [3]:

$$2c' = 1.531\ X\ 10^{-10}\ m \tag{14.527}$$

Substitution of Eqs. (14.523-14.524) into Eq. (13.62) gives:

$$b = c = 1.54616a_0 = 8.18192\ X\ 10^{-11}\ m \tag{14.528}$$

Substitution of Eqs. (14.523-14.524) into Eq. (13.63) gives:

$$e = 0.68600 \tag{14.529}$$

The nucleus of the C atoms comprise the foci of each H_2-type ellipsoidal MO. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $C_{alkane}2sp^3$ HO are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where for methylene bonds $r_n = r_{alkane2sp^3} = r_{methylene2sp^3} = 0.81549a_0$ is the radius of the $C_{alkane}2sp^3$ shell given by Eq. (14.519). Substitution of Eqs. (14.523-14.524) into Eq. (13.261) gives:

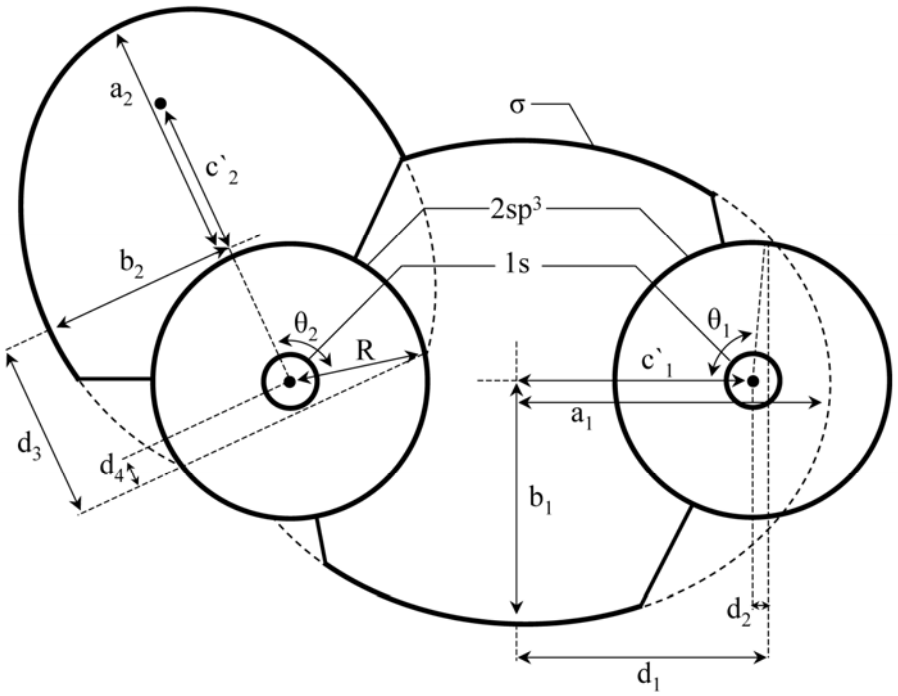
$$\theta' = 56.41° \tag{14.530}$$

Then, the angle $\theta_{C-C_{alkane}2sp^3HO}$ the radial vector of the $C2sp^3$ HO makes with the internuclear axis is:

$$\theta_{C-C_{alkane}2sp^3HO} = 180° - 56.41° = 123.59° \tag{14.531}$$

as shown in Figure 14.16.

Figure 14.16. The cross section of one $C-C$-bond MO (σ MO) and one $C-H$-bond MO of C_nH_{2n+2} showing the axes, angles, and point of intersection of each H_2-type ellipsoidal MO with the corresponding $C_{alkane}2sp^3$ HO. The continuation of each H_2-type-ellipsoidal-MO basis element of the $C-C$ bond and the $C-H$-bond beyond the intersection point with each $C_{alkane}2sp^3$ shell and σ MO is shown as dashed since each only serves to solve the energy match with the $C_{alkane}2sp^3$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of each intersection point. The actual charge density is shown by the solid lines. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, $d_1 : d_{C-C_{alkane},H_2MO}$, $\theta_1 : \theta_{C-C_{alkane}2sp^3HO}$, $d_2 : d_{C-C_{alkane}2sp^3HO}$, $R : r_{alkaneC2sp^3}$, $d_3 : d_{C-H_{alkane},H_2MO}$, $\theta_2 : \theta_{C-H_{alkane}2sp^3HO}$, and $d_4 : d_{C-H_{alkane}2sp^3HO}$.



Consider the right-hand intersection point. The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{C-C_{alkane},H_2MO}$ satisfies the following relationship:

$$r_{alkane2sp^3}\sin\theta_{C-C_{alkane}2sp^3HO} = 0.81549a_0\sin\theta_{C-C_{alkane}2sp^3HO} = b\sin\theta_{C-C_{alkane},H_2MO} \tag{14.532}$$

such that

$$\theta_{C-C_{alkane},H_2MO} = \sin^{-1}\frac{0.81549a_0\sin\theta_{C-C_{alkane}2sp^3HO}}{b} = \sin^{-1}\frac{0.81549a_0\sin 123.59°}{b} \tag{14.533}$$

with the use of Eq. (14.531). Substitution of Eq. (14.528) into Eq. (14.533) gives:

$$\theta_{C-C_{alkane},H_2MO} = 26.06° \tag{14.534}$$

Then, the distance d_{C-C_{alkane},H_2MO} along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by

$$d_{C-C_{alkane},H_2MO} = a\cos\theta_{C-C_{alkane},H_2MO} \tag{14.535}$$

Substitution of Eqs. (14.523) and (14.534) into Eq. (14.535) gives:

$$d_{C-C_{alkane},H_2MO} = 1.90890a_0 = 1.01015\ X\ 10^{-10}\ m \tag{14.536}$$

The distance $d_{C-C_{alkane}2sp^3HO}$ along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals is given by:

$$d_{C-C_{alkane}2sp^3HO} = d_{C-C_{alkane},H_2MO} - c' \tag{14.537}$$

Substitution of Eqs. (14.524) and (14.536) into Eq. (14.537) gives:

$$d_{C-C_{alkane}2sp^3HO} = 0.45117a_0 = 2.38748\ X\ 10^{-11}\ m \tag{14.538}$$

FORCE BALANCE OF THE CH_3 MOs OF CONTINUOUS-CHAIN ALKANES

Each of the two CH_3 MOs must comprise three equivalent $C-H$ bonds with each comprising 75% of a H_2-type ellipsoidal MO and a $C2sp^3$ HO as given by Eq. (13.540).

$$3\left[1\ C2sp^3 + 0.75\ H_2\ MO\right] \rightarrow CH_3\ MO \tag{14.539}$$

The force balance of the CH_3 MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.539) and the energy matching condition between the hydrogen and $C2sp^3$ HO components of the MO.

The force constant k' to determine the ellipsoidal parameter c' of the each H_2-type-ellipsoidal-MO component of the CH_3 MO in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus c' is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $C-H$-bond MO. Since each of the three prolate spheroidal $C-H$-bond MOs comprises an H_2-type-ellipsoidal MO that transitions to the $C_{alkane}2sp^3$ HO of C_nH_{2n+2}, the energy $E\left(C_{alkane},2sp^3\right)$ of Eq. (14.512) adds to that of the three corresponding H_2-type ellipsoidal MOs to give the total energy of the CH_3 MO. From the energy equation and the relationship between the axes, the dimensions of the CH_3 MO are solved.

The energy components of V_e, V_p, T, and V_m are the same as those of methyl radical, three times those of CH corresponding to the three $C-H$ bonds except that energy of the $C_{alkane}2sp^3$ HO is used. Since each prolate spheroidal H_2-type MO transitions to the $C_{alkane}2sp^3$ HO and the energy of the $C_{alkane}2sp^3$ shell must remain constant and equal to the $E\left(C_{alkane},2sp^3\right)$ given by Eq. (14.512), the total energy $E_{T_{alkane}}\left(CH_3\right)$ of the CH_3 MO is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $C_{alkane}2sp^3$ HO and the three H_2-type ellipsoidal MOs that forms the CH_3 MO as given by Eq. (14.539). Using Eq. (13.431) or Eq. (13.541), $E_{T_{alkane}}\left(CH_3\right)$ is given by:

$$E_{T_{alkane}}\left(CH_3\right) = E_T + E\left(C_{alkane},2sp^3\right) = -\frac{3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right] - 15.56407\ eV \tag{14.540}$$

$E_{T_{alkane}}\left(CH_3\right)$ given by Eq. (14.540) is set equal to three times the energy of the H_2-type ellipsoidal MO minus two times the Coulombic energy of H given by Eq. (13.542):

$$E_T\left(CH_3\right) = -\frac{3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right] - 15.56407\ eV = -67.69450\ eV \tag{14.541}$$

From the energy relationship given by Eq. (14.541) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the CH_3 MO can be solved.

Substitution of Eq. (13.60) into Eq. (14.541) gives:

$$\frac{3e^2}{8\pi\varepsilon_0\sqrt{\frac{2aa_0}{3}}}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{2aa_0}{3}}}{a-\sqrt{\frac{2aa_0}{3}}}-1\right]=e52.13044 \tag{14.542}$$

The most convenient way to solve Eq. (14.542) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a=1.64920a_0=8.72720\ X\ 10^{-11}\ m \tag{14.543}$$

Substitution of Eq. (14.543) into Eq. (14.60) gives:

$$c'=1.04856a_0=5.54872\ X\ 10^{-11}\ m \tag{14.544}$$

The internuclear distance given by multiplying Eq. (14.544) by two is:

$$2c'=2.09711a_0=1.10974\ X\ 10^{-10}\ m \tag{14.545}$$

The experimental $C-H$ bond distance of propane is [3]:

$$2c'=1.107\ X\ 10^{-10}\ m \tag{14.546}$$

Substitution of Eqs. (14.543-14.544) into Eq. (14.62) gives:

$$b=c=1.27295a_0=6.73616\ X\ 10^{-11}\ m \tag{14.547}$$

Substitution of Eqs. (14.543-14.544) into Eq. (14.63) gives:

$$e=0.63580 \tag{14.548}$$

The nucleus of the H atom and the nucleus of the C atom comprise the foci of each H_2-type ellipsoidal MO. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $C_{alkane}2sp^3$ HO are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where $r_n=r_{alkane2sp^3}=0.86359a_0$ is the radius of the $C_{alkane}2sp^3$ shell. Substitution of Eqs. (14.543-14.544) into Eq. (13.261) gives:

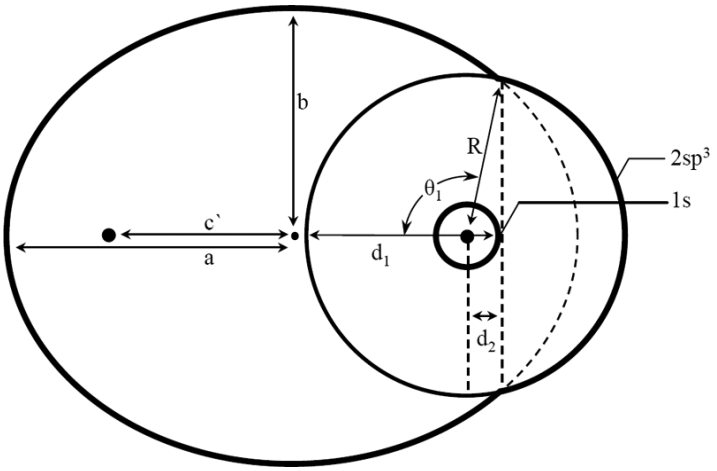
$$\theta'=77.49° \tag{14.549}$$

Then, the angle $\theta_{C-H_{alkane}2sp^3HO}$ the radial vector of the $C2sp^3$ HO makes with the internuclear axis is:

$$\theta_{C-H_{alkane}2sp^3HO}=180°-77.49°=102.51° \tag{14.550}$$

as shown in Figure 14.17.

Figure 14.17. The cross section of one $C-H$-bond MO of C_nH_{2n+2} showing the axes, angles, and point of intersection of the H_2-type ellipsoidal MO with the $C_{alkane}2sp^3$ HO. The continuation of the H_2-type-ellipsoidal-MO basis element beyond the intersection point with the $C_{alkane}2sp^3$ shell is shown as dashed since it only serves to solve the energy match with the $C_{alkane}2sp^3$ shell and does not represent charge density. Similarly, the vertical dashed line only designates the parameters of the intersection point. The actual charge density is shown by the solid lines. Legend: a: semimajor axis, b: semiminor axis, c': internuclear distance, $d_1:d_{C-H_{alkane},H_2MO}$, $\theta_1:\theta_{C-H_{alkane}2sp^3HO}$, $d_2:d_{C-H_{alkane}2sp^3HO}$, and $R:r_{alkane2sp^3}$.



The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t = \theta_{C-H_{alkane},H_2MO}$ satisfies the following relationship:

$$r_{alkane2sp^3}\sin\theta_{C-H_{alkane}2sp^3HO} = 0.86359a_0\sin\theta_{C-H_{alkane}2sp^3HO} = b\sin\theta_{C-H_{alkane},H_2MO} \tag{14.551}$$

such that

$$\theta_{C-H_{alkane},H_2MO} = \sin^{-1}\frac{0.86359a_0\sin\theta_{C-H_{alkane}2sp^3HO}}{b} = \sin^{-1}\frac{0.86359a_0\sin 102.51°}{b} \tag{14.552}$$

with the use of Eq. (14.550). Substitution of Eq. (14.547) into Eq. (14.552) gives:

$$\theta_{C-H_{alkane},H_2MO} = 41.48° \tag{14.553}$$

Then, the distance d_{C-H_{alkane},H_2MO} along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$d_{C-H_{alkane},H_2MO} = a\cos\theta_{C-H_{alkane},H_2MO} \tag{14.554}$$

Substitution of Eqs. (14.543) and (14.553) into Eq. (14.554) gives:

$$d_{C-H_{alkane},H_2MO} = 1.23564a_0 = 6.53871\ X\ 10^{-11}\ m \tag{14.555}$$

The distance $d_{C-H_{alkane}2sp^3HO}$ along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals is given by

$$d_{C-H_{alkane}2sp^3HO} = d_{C-H_{alkane},H_2MO} - c' \tag{14.556}$$

Substitution of Eqs. (14.544) and (14.555) into Eq. (14.556) gives:

$$d_{C-H_{alkane}2sp^3HO} = 0.18708a_0 = 9.89999\ X\ 10^{-12}\ m \tag{14.557}$$

BOND ANGLE OF THE CH_3 AND CH_2 GROUPS

Each CH_3 MO comprises a linear combination of three $C-H$-bond MOs. Each $C-H$-bond MO comprises the superposition of a H_2-type ellipsoidal MO and the $C_{alkane}2sp^3$ HO. A bond is also possible between the two H atoms of the $C-H$ bonds. Such $H-H$ bonding would decrease the $C-H$ bond strength since electron density would be shifted from the $C-H$ bonds to the $H-H$ bond. Thus, the bond angle between the two $C-H$ bonds is determined by the condition that the total energy of the H_2-type ellipsoidal MO between the terminal H atoms of the $C-H$ bonds is zero. From Eqs. (11.79) and (13.228), the distance from the origin to each focus of the $H-H$ ellipsoidal MO is:

$$c' = a\sqrt{\frac{\hbar^2 4\pi\varepsilon_0}{m_e e^2 2a}} = \sqrt{\frac{aa_0}{2}} \tag{14.558}$$

The internuclear distance from Eq. (14.558) is:

$$2c' = 2\sqrt{\frac{aa_0}{2}} \tag{14.559}$$

The length of the semiminor axis of the prolate spheroidal $H-H$ MO $b=c$ is given by Eq. (14.62).

The bond angle of the CH_3 groups of C_nH_{2n+2} is derived by using the orbital composition and an energy matching factor as in the case with the CH_3 radical. Since each pair of H_2-type ellipsoidal MOs initially comprise 75% of the H electron density of H_2 and the energy of each H_2-type ellipsoidal MO is matched to that of the $C_{alkane}2sp^3$ HO, the component energies and the total energy E_T of the $H-H$ bond are given by Eqs. (13.67-13.73) except that V_e, T, and V_m are corrected for the hybridization-energy-matching factor of 0.86359. Hybridization with 25% electron donation to the $C-C$-bond gives rise to the $C_{alkane}2sp^3$ HO-shell Coulombic energy $E_{Coulomb}\left(C_{alkane},2sp^3\right)$ given by Eq. (14.515). The corresponding normalization factor for determining the zero of the total $H-H$ bond energy is given by the ratio of $15.75493\ eV$, the magnitude of $E_{Coulomb}\left(C_{alkane},2sp^3\right)$ given by Eq. (14.515), and $13.605804\ eV$, the magnitude of the Coulombic energy between the electron and proton of H given by Eq. (1.264). The hybridization energy factor $C_{alkaneC2sp^3HO}$ is:

$$C_{alkaneC2sp^3HO} = \frac{\frac{e^2}{8\pi\varepsilon_0 a_0}}{\frac{e^2}{8\pi\varepsilon_0 r_{alkane2sp^3}}} = \frac{\frac{e^2}{8\pi\varepsilon_0 a_0}}{\frac{e^2}{8\pi\varepsilon_0 0.86359a_0}} = \frac{13.605804\ eV}{15.75493\ eV} = 0.86359 \tag{14.560}$$

Substitution of Eq. (14.558) into Eq. (13.233) with the hybridization factor of 0.86359 gives:

$$0=\left[\begin{array}{l}\dfrac{-e^2}{8\pi\varepsilon_0\sqrt{\dfrac{aa_0}{2}}}\left[(0.86359)^{-1}\left(\dfrac{3}{2}-\dfrac{3}{8}\dfrac{a_0}{a}\right)\ln\dfrac{a+\sqrt{\dfrac{aa_0}{2}}}{a-\sqrt{\dfrac{aa_0}{2}}}-1\right]\left[1+\sqrt{\dfrac{2\hbar\sqrt{\dfrac{0.75e^2}{4\pi\varepsilon_0 a^3}}}{m_e c^2}}\right] \\ +\hbar\sqrt{\dfrac{\dfrac{0.75e^2}{8\pi\varepsilon_0 a^3}-\dfrac{e^2}{8\pi\varepsilon_0\left(a+c'\right)^3}}{0.5m_p}}\end{array}\right] \tag{14.561}$$

From the energy relationship given by Eq. (14.561) and the relationship between the axes given by Eqs. (14.558-14.559) and (14.62-14.63), the dimensions of the $H-H$ MO can be solved.

The most convenient way to solve Eq. (14.561) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a=5.8660a_0=3.1042\ X\ 10^{-10}\ m \tag{14.562}$$

Substitution of Eq. (14.562) into Eq. (14.558) gives:

$$c'=1.7126a_0=9.0627\ X\ 10^{-11}\ m \tag{14.563}$$

The internuclear distance given by multiplying Eq. (14.563) by two is:

$$2c'=3.4252a_0=1.8125\ X\ 10^{-10}\ m \tag{14.564}$$

Substitution of Eqs. (14.562-14.563) into Eq. (14.62) gives:

$$b=c=5.6104a_0=2.9689\ X\ 10^{-10}\ m \tag{14.565}$$

Substitution of Eqs. (14.562-14.563) into Eq. (14.63) gives:

$$e=0.2920 \tag{14.566}$$

Using $2c'_{H-H}$ (Eq. (14.564)), the distance between the two H atoms when the total energy of the corresponding MO is zero (Eq. (14.561)), and $2c'_{C-H}$, the internuclear distance of each $C-H$ bond, the corresponding bond angle can be determined from the law of cosines. Since the internuclear distance of each $C-H$ bond of CH_3 (Eq. (14.545)) and CH_2 (Eq. (14.597)) are sufficiently equivalent, the bond angle determined with either is within experimental error of being the same. Using, Eqs. (13.242), (14.545), and (14.564), the bond angle θ between the $C-H$ bonds is:

$$\theta=\cos^{-1}\left(\frac{2\left(2.09711\right)^2-\left(3.4252\right)^2}{2\left(2.09711\right)^2}\right)=\cos^{-1}\left(-0.33383\right)=109.50° \tag{14.567}$$

The experimental angle between the $C-H$ bonds is [19]:

$$\theta=109.3° \tag{14.568}$$

The CH_3 radical has a pyramidal structure with the carbon atom along the z-axis at the apex and the hydrogen atoms at the base in the xy-plane. The distance $d_{origin-H}$ from the origin to the nucleus of a hydrogen atom given by Eqs. (14.564) and (13.412) is:

$$d_{origin-H}=1.97754a_0 \tag{14.569}$$

The height along the z-axis of the pyramid from the origin to C nucleus d_{height} given by Eqs. (13.414), (14.545), and (14.569) is

$$d_{height}=0.69800a_0 \tag{14.570}$$

The angle θ_v of each $C-H$ bond from the z-axis given by Eqs. (13.416), (14.569), and (14.570) is:

$$\theta_v=70.56° \tag{14.571}$$

The $C-C$ bond is along the z-axis. Thus, the bond angle θ_{C-C-H} between the internuclear axis of the $C-C$ bond and a H atom of the methyl groups is given by:

$$\theta_{C-C-H}=180-\theta_v \tag{14.572}$$

Substitution of Eq. (14.571) into Eq. (14.572) gives:

$$\theta_{C-C-H}=109.44° \tag{14.573}$$

The experimental angle between the $C-C-H$ bonds is [19]:

$$\theta_{C-C-H}=109.3° \tag{14.574}$$

The C_nH_{2n+2} MOs shown in Figures 14.18-14.28 were rendered using these parameters. A minimum energy is obtained with a staggered configuration consistent with observations [3].

ENERGIES OF THE CH_3 GROUPS

The energies of each CH_3 group of C_nH_{2n+2} are given by the substitution of the semiprincipal axes (Eqs. (14.543-14.544) and (14.547)) into the energy equations of methyl radical (Eqs. (13.556-13.560)), with the exception that $E\left(C_{alkane},2sp^3\right)$ (Eq. (14.514)) replaces $E\left(C,2sp^3\right)$ in Eq. (13.560).

$$V_e = 3\left(0.91771\right)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -107.32728\ eV \tag{14.575}$$

$$V_p = \frac{3e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 38.92728\ eV \tag{14.576}$$

$$T = 3\left(0.91771\right)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 32.53914\ eV \tag{14.577}$$

$$V_m = 3\left(0.91771\right)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -16.26957\ eV \tag{14.578}$$

$$E_{T_{alkane}}\left(CH_3\right) = \begin{pmatrix} -\frac{3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right] \\ -15.56407\ eV \end{pmatrix} = -67.69451\ eV \tag{14.579}$$

where $E_{T_{alkane}}\left(CH_3\right)$ is given by Eq. (14.540) which is reiteratively matched to Eq. (13.542) within five-significant-figure round off error.

VIBRATION OF THE $^{12}CH_3$ GROUPS

The vibrational energy levels of the $C-H$ bonds of CH_3 in C_nH_{2n+2} may be solved as three equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

THE DOPPLER ENERGY TERMS OF THE $^{12}CH_3$ GROUPS

The equations of the radiation reaction force of the methyl groups in C_nH_{2n+2} are the same as those of the methyl radical with the substitution of the methyl-group parameters. Using Eq. (13.561), the angular frequency of the reentrant oscillation in the transition state is:

$$\omega = \sqrt{\frac{\frac{0.75e^2}{4\pi\varepsilon_0 b^3}}{m_e}} = 2.49286\ X\ 10^{16}\ rad/s \tag{14.580}$$

where b is given by Eq. (14.547). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\overline{E}_K = \hbar\omega = \hbar 2.49286\ X\ 10^{16}\ rad/s = 16.40846\ eV \tag{14.581}$$

In Eq. (11.181), substitution of $E_T\left(H_2\right)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each H_2-type MO, for E_{hv}, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.581) for $\overline{E}_K$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$\overline{E}_D \cong E_{hv}\sqrt{\frac{2\overline{E}_K}{Mc^2}} = -31.63537\ eV\sqrt{\frac{2e\left(16.40846\ eV\right)}{m_e c^2}} = -0.25352\ eV \tag{14.582}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of CH_3 due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\overline{E}_{osc}$, is given by the sum of the corresponding energies, $\overline{E}_D$ given by Eq. (14.582) and $\overline{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of each $C-H$ bond. Using ω_e given by Eq. (13.458) for $\overline{E}_{Kvib}$ of the *transition* state having three independent bonds, $\overline{E}'_{alkane\ osc}\left(^{12}CH_3\right)$ per bond is:

$$\overline{E}'_{alkane\ osc}\left(^{12}CH_3\right) = \overline{E}_D + \overline{E}_{Kvib} = \overline{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{14.583}$$

$$\overline{E}'_{alkane\ osc}\left(^{12}CH_3\right) = -0.25352\ eV + \frac{1}{2}\left(0.35532\ eV\right) = -0.07586\ eV \tag{14.584}$$

Given that the vibration and reentrant oscillation is for three $C-H$ bonds, $\bar{E}_{alkane\ osc}\left({}^{12}CH_3\right)$, is:

$$\bar{E}_{alkane\ osc}\left({}^{12}CH_3\right)=3\left(\bar{E}_D+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)=3\left(-0.25352\ eV+\frac{1}{2}\left(0.35532\ eV\right)\right)=-0.22757\ eV \tag{14.585}$$

TOTAL BOND ENERGIES OF THE ${}^{12}CH_3$ GROUPS

$E_{alkaneT+osc}\left({}^{12}CH_3\right)$, the total energy of each ${}^{12}CH_3$ group including the Doppler term, is given by the sum of $E_{T_{alkane}}\left(CH_3\right)$ (Eq. (14.579)) and $\bar{E}_{alkane\ osc}\left({}^{12}CH_3\right)$ given by Eq. (14.585).

$$E_{alkaneT+osc}\left({}^{12}CH_3\right)=V_e+T+V_m+V_p+E\left(C_{alkane},2sp^3\right)+\bar{E}_{alkane\ osc}\left({}^{12}CH_3\right)=E_{T_{alkane}}\left(CH_3\right)+\bar{E}_{alkane\ osc}\left({}^{12}CH_3\right) \tag{14.586}$$

$$\begin{aligned}E_{alkaneT+osc}\left({}^{12}CH_3\right)&=\left\{\begin{array}{l}\left(\frac{-3e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-15.56407\ eV\right)\\ -3\left(\left(31.63536831\ eV\right)\sqrt{\frac{2\hbar\sqrt{\frac{3}{4}\frac{e^2}{4\pi\varepsilon_0 b^3}}}{m_e c^2}}-\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)\end{array}\right\}\\&=-67.69450\ eV-3\left(0.25352\ eV-\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)\end{aligned} \tag{14.587}$$

From Eqs. (14.585-14.587), the total energy of each ${}^{12}CH_3$ is:

$$\begin{aligned}E_{alkaneT+osc}\left({}^{12}CH_3\right)&=-67.69450\ eV+\bar{E}_{alkane\ osc}\left({}^{12}CH_3\right)\\&=-67.69450\ eV-3\left(0.25352\ eV-\frac{1}{2}\left(0.35532\ eV\right)\right)=-67.92207\ eV\end{aligned} \tag{14.588}$$

where ω_e given by Eq. (13.458) was used for the $\hbar\sqrt{\frac{k}{\mu}}$ term.

The total CH_3 bond dissociation energy, $E_{D_{alkane}}\left({}^{12}CH_3\right)$ is given by the sum of the initial $C2sp^3$ HO energy, $E\left(C,2sp^3\right)$ (Eq. (14.146)), and three times the energy of the hydrogen atom, $E_D\left(H\right)$ (Eq. (13.154)), minus $E_{alkaneT+osc}\left({}^{12}CH_3\right)$ (Eq. (14.588)).

$$E_{D_{alkane}}\left({}^{12}CH_3\right)=E\left(C,2sp^3\right)+3E(H)-E_{alkaneT+osc}\left({}^{12}CH_3\right) \tag{14.589}$$

Thus, the total ${}^{12}CH_3$ bond dissociation energy, $E_{D_{alkane}}\left({}^{12}CH_3\right)$ is:

$$\begin{aligned}E_{D_{alkane}}\left({}^{12}CH_3\right)&=-\left(14.63489\ eV+3\left(13.59844\ eV\right)\right)-\left(E_{alkaneT+osc}\left({}^{12}CH_2\right)\right)\\&=-55.43021\ eV-\left(-67.92207\ eV\right)=12.49186\ eV\end{aligned} \tag{14.590}$$

FORCE BALANCE OF THE CH_2 MOs OF CONTINUOUS-CHAIN ALKANES

Each of the CH_2 MOs must comprise two equivalent $C-H$ bonds with each comprising 75% of a H_2-type ellipsoidal MO and a $C2sp^3$ HO as given by Eq. (13.494).

$$2\left[1\ C2sp^3+0.75\ H_2\ MO\right]\rightarrow CH_2\ MO \tag{14.591}$$

The force balance of each CH_2 MO is determined by the boundary conditions that arise from the linear combination of orbitals according to Eq. (14.591) and the energy matching condition between the hydrogen and $C2sp^3$ HO components of the MO.

The force constant k' to determine the ellipsoidal parameter c' of the each H_2-type-ellipsoidal-MO component of the CH_2 MO in terms of the central force of the foci is given by Eq. (13.59). The distance from the origin of each $C-H$-bond MO to each focus c' is given by Eq. (13.60). The internuclear distance is given by Eq. (13.61). The length of the semiminor axis of the prolate spheroidal $C-H$-bond MO $b=c$ is given by Eq. (13.62). The eccentricity, e, is given by Eq. (13.63). The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of each $C-H$-bond MO. Since each of the two prolate spheroidal $C-H$-bond MOs comprises an H_2-type-ellipsoidal MO that transitions to the $C_{alkane}2sp^3$ HO of C_nH_{2n+2}, the energy $E\left(C_{alkane},2sp^3\right)$ of Eq. (14.512) adds to that of the two corresponding H_2-type ellipsoidal

MOs to give the total energy of the CH_2 MO. From the energy equation and the relationship between the axes, the dimensions of the CH_2 MO are solved.

The energy components of V_e, V_p, T, and V_m are the same as those of dihydrogen carbide radical, two times those of CH corresponding to the two $C-H$ bonds except that energy of the $C_{alkane}2sp^3$ HO is used. Since each prolate spheroidal H_2-type MO transitions to the $C_{alkane}2sp^3$ HO and the energy of the $C_{alkane}2sp^3$ shell treated independently must remain constant and equal to the $E\left(C_{alkane},2sp^3\right)$ given by Eq. (14.512), the total energy $E_{T_{alkane}}\left(CH_2\right)$ of the CH_2 MO is given by the sum of the energies of the orbitals corresponding to the composition of the linear combination of the $C_{alkane}2sp^3$ HO and the two H_2-type ellipsoidal MOs that forms the CH_2 MO as given by Eq. (14.591). Using Eq. (13.431) or Eq. (13.495), $E_{T_{alkane}}\left(CH_2\right)$ is given by:

$$E_{T_{alkane}}\left(CH_2\right)=E_T+E\left(C_{alkane},2sp^3\right)=-\frac{2e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-15.56407\ eV \tag{14.592}$$

$E_{T_{alkane}}\left(CH_2\right)$ given by Eq. (14.592) is set equal to two times the energy of the H_2-type ellipsoidal MO minus the Coulombic energy of H given by Eq. (13.496).

$$E_T\left(CH_2\right)=-\frac{2e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-15.56407\ eV=-49.66493\ eV \tag{14.593}$$

From the energy relationship given by Eq. (14.593) and the relationship between the axes given by Eqs. (13.60-13.63), the dimensions of the CH_2 MO can be solved.

Substitution of Eq. (13.60) into Eq. (14.593) gives:

$$\frac{2e^2}{8\pi\varepsilon_0\sqrt{\frac{2aa_0}{3}}}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{2aa_0}{3}}}{a-\sqrt{\frac{2aa_0}{3}}}-1\right]=e34.10086 \tag{14.594}$$

The most convenient way to solve Eq. (14.594) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is

$$a=1.67122a_0=8.84370\ X\ 10^{-11}\ m \tag{14.595}$$

Substitution of Eq. (14.595) into Eq. (14.60) gives:

$$c'=1.05553a_0=5.58563\ X\ 10^{-11}\ m \tag{14.596}$$

The internuclear distance given by multiplying Eq. (14.596) by two is:

$$2c'=2.11106a_0=1.11713\ X\ 10^{-10}\ m \tag{14.597}$$

The experimental $C-H$ bond distance of butane is [3]:

$$2c'=1.117\ X\ 10^{-10}\ m \tag{14.598}$$

Substitution of Eqs. (14.595-14.596) into Eq. (14.62) gives:

$$b=c=1.29569a_0=6.85652\ X\ 10^{-11}\ m \tag{14.599}$$

Substitution of Eqs. (14.595-14.596) into Eq. (14.63) gives:

$$e=0.63159 \tag{14.600}$$

The nucleus of the H atom and the nucleus of the C atom comprise the foci of each H_2-type ellipsoidal MO. The parameters of the point of intersection of the H_2-type ellipsoidal MO and the $C_{alkane}2sp^3$ HO are given by Eqs. (13.84-13.95) and (13.261-13.270). The polar intersection angle θ' is given by Eq. (13.261) where $r_n=r_{methylene2sp^3}=0.81549a_0$ is the radius of the $C_{methylene}2sp^3$ shell (Eq. (14.521)). Substitution of Eqs. (14.595-14.596) into Eq. (13.261) gives:

$$\theta'=68.47° \tag{14.601}$$

Then, the angle $\theta_{C-H_{alkane}2sp^3HO}$ the radial vector of the $C2sp^3$ HO makes with the internuclear axis is:

$$\theta_{C-H_{alkane}2sp^3HO}=180°-68.47°=111.53° \tag{14.602}$$

as shown in Figure 14.17. The Cartesian **i**-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian **j**-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{C-H_{alkane},H_2MO}$ satisfies the following relationship:

$$r_{alkane2sp^3}\sin\theta_{C-H_{alkane}2sp^3HO}=0.81549a_0\sin\theta_{C-H_{alkane}2sp^3HO}=b\sin\theta_{C-H_{alkane},H_2MO} \tag{14.603}$$

such that

$$\theta_{C-H_{alkane},H_2MO} = \sin^{-1}\frac{0.81549a_0\sin\theta_{C-H_{alkane}2sp^3HO}}{b} = \sin^{-1}\frac{0.81549a_0\sin 111.53°}{b} \tag{14.604}$$

with the use of Eq. (14.602). Substitution of Eq. (14.599) into Eq. (14.604) gives:

$$\theta_{C-H_{alkane},H_2MO} = 35.84° \tag{14.605}$$

Then, the distance d_{C-H_{alkane},H_2MO} along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$d_{C-H_{alkane},H_2MO} = a\cos\theta_{C-H_{alkane},H_2MO} \tag{14.606}$$

Substitution of Eqs. (14.595) and (14.605) into Eq. (14.606) gives:

$$d_{C-H_{alkane},H_2MO} = 1.35486a_0 = 7.16963\ X\ 10^{-11}\ m \tag{14.607}$$

The distance $d_{C-H_{alkane}2sp^3HO}$ along the internuclear axis from the origin of the C atom to the point of intersection of the orbitals is given by:

$$d_{C-H_{alkane}2sp^3HO} = d_{C-H_{alkane},H_2MO} - c' \tag{14.608}$$

Substitution of Eqs. (14.596) and (14.605) into Eq. (14.608) gives:

$$d_{C-H_{alkane}2sp^3HO} = 0.29933a_0 = 1.58400\ X\ 10^{-11}\ m \tag{14.609}$$

The charge-density in each $C-C$-bond MO is increased by a factor of 0.25 with the formation of the $C_{alkane}2sp^3$ HOs each having a smaller radius. Using the orbital composition of the $C-C$-bond MOs (Eq. (14.504)), CH_3 groups (Eq. (14.539)), and the CH_2 groups (Eq. (14.591)), the radii of $C1s = 0.17113a_0$ (Eq. (10.51)), $C_{alkane}2sp^3 = 0.86359a_0$ (Eq. (14.514)), and $C_{alkane}2sp^3 = C_{methylene}2sp^3 = 0.81549a_0$ (Eq. (14.521)) shells, the parameters of the $C-C$-bonds (Eqs. (13.3-13.4), (14.523-14.525), and (14.528-14.538)), the parameters of the $C-H$-bond MOs of the CH_3 groups (Eqs. (13.3-13.4), (14.544-14.545), and (14.547-14.557)), the parameters of the $C-H$-bond MOs of the CH_2 groups (Eqs. (13.3-13.4), (14.595-14.597), and (14.599-14.609)), and the bond-angle parameters (Eqs. (14.562-14.574)), the charge-density of the C_nH_{2n+2} MO comprising the linear combination $2n+2$ $C-H$-bond MOs and $n-1$ $C-C$-bond MOs, each bridging one or more methyl or methylene groups is shown for representative cases where data was available [17-18]. Propane, butane, pentane, hexane, heptane, octane, nonane, decane, undecane, dodecane, and octadecane are shown in Figures 14.18-14.28, respectively. Each $C-H$-bond MO comprises a H_2-type ellipsoidal MO and a $C_{alkane}2sp^3$ HO having the dimensional diagram shown in Figure 14.16. Each $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{alkane}2sp^3$ HOs having the dimensional diagram shown in Figure 14.17.

ENERGIES OF THE CH_2 GROUPS

The energies of each CH_2 group of C_nH_{2n+2} are given by the substitution of the semiprincipal axes (Eqs. (14.595-14.596) and (14.599)) into the energy equations of dihydrogen carbide radical (Eqs. (13.510-13.514)), with the exception that $E\left(C_{alkane},2sp^3\right)$ (Eq. (14.512)) replaces $E\left(C,2sp^3\right)$ in Eq. (13.514):

$$V_e = 2\left(0.91771\right)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -70.41425\ eV \tag{14.610}$$

$$V_p = \frac{2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = 25.78002\ eV \tag{14.611}$$

$$T = 2\left(0.91771\right)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = 21.06675\ eV \tag{14.612}$$

$$V_m = 2\left(0.91771\right)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -10.53337\ eV \tag{14.613}$$

$$E_{T_{alkane}}\left(CH_2\right) = -\frac{2e^2}{8\pi\varepsilon_0 c'}\left[\left(0.91771\right)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right] - 15.56407\ eV = -49.66493\ eV \tag{14.614}$$

where $E_{T_{alkane}}\left(CH_2\right)$ is given by Eq. (14.592) which is reiteratively matched to Eq. (13.496) within five-significant-figure round off error.

VIBRATION OF THE $^{12}CH_2$ GROUPS

The vibrational energy levels of the $C-H$ bonds of CH_2 in C_nH_{2n+2} may be solved as two equivalent coupled harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

THE DOPPLER ENERGY TERMS OF THE $^{12}CH_2$ GROUPS

The equations of the radiation reaction force of the methylene groups in C_nH_{2n+2} are the same as those of the dihydrogen carbide radical with the substitution of the methylene-group parameters. Using Eq. (13.515), the angular frequency of the reentrant oscillation in the transition state is:

$$\omega = \sqrt{\frac{0.75e^2}{\frac{4\pi\varepsilon_0 b^3}{m_e}}} = 2.42751\ X\ 10^{16}\ rad/s \tag{14.615}$$

where b is given by Eq. (14.599). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K = \hbar\omega = \hbar 2.42751\ X\ 10^{16}\ rad/s = 15.97831\ eV \tag{14.616}$$

In Eq. (11.181), substitution of $E_T(H_2)$ (Eqs. (11.212) and (13.75)), the maximum total energy of each H_2-type MO, for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.616) for $\bar{E}_K$ gives the Doppler energy of the electrons of each of the three bonds for the reentrant orbit:

$$\bar{E}_D \cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}} = -31.63537\ eV\sqrt{\frac{2e(15.97831\ eV)}{m_e c^2}} = -0.25017\ eV \tag{14.617}$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of CH_2 due to the reentrant orbit of each bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (14.617) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of each $C-H$ bond. Using ω_e given by Eq. (13.458) for $\bar{E}_{Kvib}$ of the transition state having two independent bonds, $\bar{E}'_{alkane\ osc}(^{12}CH_2)$ per bond is:

$$\bar{E}'_{alkane\ osc}(^{12}CH_2) = \bar{E}_D + \bar{E}_{Kvib} = \bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \tag{14.618}$$

$$\bar{E}'_{alkane\ osc}(^{12}CH_2) = -0.25017\ eV + \frac{1}{2}(0.35532\ eV) = -0.07251\ eV \tag{14.619}$$

Given that the vibration and reentrant oscillation is for two $C-H$ bonds, $\bar{E}_{alkane\ osc}(^{12}CH_2)$, is:

$$\bar{E}_{alkane\ osc}(^{12}CH_2) = 2\left(\bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) = 2\left(-0.25017\ eV + \frac{1}{2}(0.35532\ eV)\right) = -0.14502\ eV \tag{14.620}$$

TOTAL BOND ENERGIES OF THE $^{12}CH_2$ GROUPS

$E_{alkaneT+osc}(^{12}CH_2)$, the total energy of each $^{12}CH_2$ group including the Doppler term, is given by the sum of $E_{T_{alkane}}(CH_2)$ (Eq. (14.614)) and $\bar{E}_{alkane\ osc}(^{12}CH_2)$ given by Eq. (14.620).

$$\begin{aligned} E_{alkaneT+osc}(^{12}CH_2) &= V_e + T + V_m + V_p + E(C_{alkane}, 2sp^3) + \bar{E}_{alkane\ osc}(^{12}CH_2) \\ &= E_{T_{alkane}}(CH_2) + \bar{E}_{alkane\ osc}(^{12}CH_2) \end{aligned} \tag{14.621}$$

$$E_{alkaneT+osc}(^{12}CH_2) = \left\{ \begin{array}{l} \left(\frac{-2e^2}{8\pi\varepsilon_0 c'}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]-15.56407\ eV\right) \\ -2\left((31.63536831\ eV)\sqrt{\frac{2\hbar\sqrt{\frac{3}{4}\frac{e^2}{4\pi\varepsilon_0 b^3}}}{m_e c^2}}-\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \end{array} \right\} \tag{14.622}$$

$$= -49.66493\ eV - 2\left(0.25017\ eV - \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)$$

From Eqs. (14.620-14.622), the total energy of each $^{12}CH_2$ is:

$$\begin{aligned} E_{alkaneT+osc}\left(^{12}CH_2\right) &= -49.66493\ eV + \bar{E}_{alkane\ osc}\left(^{12}CH_2\right) \\ &= -49.66493\ eV - 2\left(0.25017\ eV - \frac{1}{2}\left(0.35532\ eV\right)\right) = -49.80996\ eV \end{aligned} \tag{14.623}$$

where ω_e given by Eq. (13.458) was used for the $\hbar\sqrt{\frac{k}{\mu}}$ term.

The derivation of the total CH_2 bond dissociation energy, $E_{D_{alkane}}\left(^{12}CH_2\right)$ follows from that of the bond dissociation energy of dihydrogen carbide radical, $E_D\left(^{12}CH_2\right)$, given by Eqs. (13.524-13.527). $E_{D_{alkane}}\left(^{12}CH_2\right)$ is given by the sum of the initial $C2sp^3$ HO energy, $E\left(C,2sp^3\right)$ (Eq. (14.146)), and two times the energy of the hydrogen atom, $E(H)$ (Eq. (13.154)), minus the sum of $E_{alkaneT+osc}\left(^{12}CH_2\right)$ (Eq. (14.623)) and $E(magnetic)$ (Eq. (13.524)):

$$E_{D_{alkane}}\left(^{12}CH_2\right) = E\left(C,2sp^3\right) + 2E(H) - E_{alkaneT+osc}\left(^{12}CH_2\right) - E\left(magnetic\right) \tag{14.624}$$

Thus, the total $^{12}CH_2$ bond dissociation energy, $E_{D_{alkane}}\left(^{12}CH_2\right)$ is:

$$\begin{aligned} E_{D_{alkane}}\left(^{12}CH_2\right) &= -\left(14.63489\ eV + 2\left(13.59844\ eV\right)\right) - \left(E_{alkaneT+osc}\left(^{12}CH_2\right) + E\left(magnetic\right)\right) \\ &= -41.83177\ eV - \left(-49.80996\ eV + 0.14803\ eV\right) = 7.83016\ eV \end{aligned} \tag{14.625}$$

SUM OF THE ENERGIES OF THE $C-C$ σ MOs AND THE HOs OF CONTINUOUS-CHAIN ALKANES

The energy components of V_e, V_p, T, V_m, and E_T of the $C-C$-bond MOs are the same as those of the CH MO except that energy of the $C_{alkane}2sp^3$ HO is used. The energies of each $C-C$-bond MO are given by the substitution of the semiprincipal axes (Eqs. (14.523-14.524) and (14.528)) into the energy equations of the CH MO (Eqs. (13.449-13.453)), with the exception that $E\left(C_{alkane},2sp^3\right)$ (Eq. (14.512)) replaces $E\left(C,2sp^3\right)$ in Eq. (13.453). The total number of $C-C$ bonds of C_nH_{2n+2} is $n-1$. Thus, the energies of the $n-1$ bonds is given by:

$$V_e = (n-1)(0.91771)\frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -(n-1)28.79214\ eV \tag{14.626}$$

$$V_p = \frac{(n-1)e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} = (n-1)9.33352\ eV \tag{14.627}$$

$$T = (n-1)(0.91771)\frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = (n-1)6.77464\ eV \tag{14.628}$$

$$V_m = (n-1)(0.91771)\frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -(n-1)3.38732\ eV \tag{14.629}$$

$$E_{T_{alkane}}(C-C,\sigma) = -\frac{(n-1)e^2}{8\pi\varepsilon_0 c'}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right] - 15.56407\ eV = -(n-1)31.63537\ eV \tag{14.630}$$

where $E_{T_{alkane}}\left(C-C,\sigma\right)$ is the total energy of the $C-C$ σ MOs given by Eq. (14.520) which is reiteratively matched to Eq. (13.75) within five-significant-figure round off error.

Since there are two carbon atoms per bond, the number of $C-C$ bonds is $n-1$, and the energy change of each $C2sp^3$ shell due to the decrease in radius with the formation of each $C-C$-bond MO is $E_{T_{alkane}}\left(C-C,2sp^3\right)$ (Eq. (14.517)), the total energy of the $C-C$-bond MOs, $E_{T_{alkane}}(C-C)$, is given by the sum of $2(n-1)E_{T_{alkane}}\left(C-C,2sp^3\right)$ and $E_{T_{alkane}}\left(C-C,\sigma\right)$, the σ MO contribution given by Eq. (14.630).

$$E_{T_{alkane}}(C-C) = 2(n-1)E_{T_{alkane}}(C-C,2sp^3) + E_{T_{alkane}}(C-C,\sigma)$$
$$= (n-1)\left(\begin{array}{l} 2(-0.92918\ eV) \\ +\left(\begin{array}{l} -\dfrac{e^2}{8\pi\varepsilon_0\sqrt{aa_0}}\left[(0.91771)\left(2-\dfrac{1}{2}\dfrac{a_0}{a}\right)\ln\dfrac{a+\sqrt{aa_0}}{a-\sqrt{aa_0}}-1\right] \\ -15.56407\ eV \end{array}\right) \end{array}\right) \quad (14.631)$$
$$= (n-1)\left(2(-0.92918\ eV)+(-31.63537\ eV)\right) = -(n-1)33.49373\ eV$$

VIBRATION OF CONTINUOUS-CHAIN ALKANES

The vibrational energy levels of the $C-C$ bonds of C_nH_{2n+2} may be solved as $n-1$ sets of coupled carbon harmonic oscillators wherein each carbon is further coupled to two or three equivalent H harmonic oscillators by developing the Lagrangian, the differential equation of motion, and the eigenvalue solutions [9] wherein the spring constants are derived from the central forces as given in the Vibration of Hydrogen-Type Molecular Ions section and the Vibration of Hydrogen-Type Molecules section.

THE DOPPLER ENERGY TERMS OF THE $C-C$-BOND MOs OF CONTINUOUS-CHAIN ALKANES

The equations of the radiation reaction force of each symmetrical $C-C$-bond MO are given by Eqs. (11.231-11.233), except the force-constant factor is 0.5 based on the force constant k' of Eq. (14.152), and the $C-C$-bond MO parameters are used. The angular frequency of the reentrant oscillation in the transition state is:

$$\omega = \sqrt{\frac{0.5e^2}{4\pi\varepsilon_0 a^3}} = 9.43699\ X\ 10^{15}\ rad/s \quad (14.632)$$

where a is given by Eq. (14.523). The kinetic energy, E_K, is given by Planck's equation (Eq. (11.127)).

$$\bar{E}_K = \hbar\omega = \hbar 9.43699\ X\ 10^{15}\ rad/s = 6.21159\ eV \quad (14.633)$$

In Eq. (11.181), substitution of $E_{T_{alkane}}(C-C)$ (Eq. (14.631)) with $n=2$ for $E_{h\nu}$, the mass of the electron, m_e, for M, and the kinetic energy given by Eq. (14.633) for $\bar{E}_K$ gives the Doppler energy of the electrons of each of the bonds for the reentrant orbit:

$$\bar{E}_D \cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{Mc^2}} = -33.49373\ eV\sqrt{\frac{2e(6.21159\ eV)}{m_e c^2}} = -0.16515\ eV \quad (14.634)$$

In addition to the electrons, the nuclei also undergo simple harmonic oscillation in the transition state at their corresponding frequency. The decrease in the energy of each $C-C$-bond MO due to the reentrant orbit of the bond in the transition state corresponding to simple harmonic oscillation of the electrons and nuclei, $\bar{E}_{osc}$, is given by the sum of the corresponding energies, $\bar{E}_D$ given by Eq. (14.634) and $\bar{E}_{Kvib}$, the average kinetic energy of vibration which is 1/2 of the vibrational energy of each $C-C$ bond. Using the ethane experimental $C-C$ $E_{vib}(\upsilon_3)$ of 993 cm^{-1} $(0.12312\ eV)$ [10] for $\bar{E}_{Kvib}$ of the transition state having $n-1$ independent bonds, $\bar{E}'_{alkane\ osc}(C-C,\sigma)$ per bond is:

$$\bar{E}'_{alkane\ osc}(C-C,\sigma) = \bar{E}_D + \bar{E}_{Kvib} = \bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \quad (14.635)$$

$$\bar{E}'_{alkane\ osc}(C-C,\sigma) = -0.16515\ eV + \frac{1}{2}(0.12312\ eV) = -0.10359\ eV \quad (14.636)$$

Given that the vibration and reentrant oscillation is for $n-1$ $C-C$ bonds, $\bar{E}_{alkane\ osc}(C-C,\sigma)$, is:

$$\bar{E}_{alkane\ osc}(C-C,\sigma) = (n-1)\left(\bar{E}_D + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right)$$
$$= (n-1)\left(-0.16515\ eV + \frac{1}{2}(0.12312\ eV)\right) = -(n-1)0.10359\ eV \quad (14.637)$$

TOTAL ENERGIES OF THE $C-C$-BOND MOs OF CONTINUOUS-CHAIN ALKANES

$E_{alkaneT+osc}(C-C)$, the total energy of the $n-1$ bonds of the $C-C$-bond MOs including the Doppler term, is given by the sum of $E_{T_{alkane}}(C-C)$ (Eq. (14.631)) and $\bar{E}_{alkane\ osc}(C-C,\sigma)$ given by Eq. (14.637).

$$
\begin{aligned}
E_{alkaneT+osc}(C-C) &= \left((n-1)\begin{pmatrix} V_e+T+V_m+V_p+E\left(C_{alkane},2sp^3\right) \\ +2E_{T_{alkane}}\left(C-C,2sp^3\right) \end{pmatrix} + \bar{E}_{alkane\ osc}(C-C,\sigma) \right) \\
&= E_{T_{alkane}}(C-C,\sigma) + 2(n-1)E_{T_{alkane}}\left(C-C,2sp^3\right) + \bar{E}_{alkane\ osc}(C-C,\sigma) \\
&= E_{T_{alkane}}(C-C) + \bar{E}_{alkane\ osc}(C-C,\sigma)
\end{aligned} \tag{14.638}
$$

$$
E_{alkaneT+osc}(C-C) = (n-1)\left\{ \begin{pmatrix} \frac{-e^2}{8\pi\varepsilon_0 c'}\left[(0.91771)\left(2-\frac{1}{2}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1 \right] \\ -15.56407\ eV + 2E_{T_{alkane}}\left(C-C,2sp^3\right) \end{pmatrix} \right\}
$$

$$
\left\{ \begin{pmatrix} 1+\sqrt{\dfrac{2\hbar\sqrt{\dfrac{1}{2}\dfrac{e^2}{4\pi\varepsilon_0 a^3}}}{m_e c^2}} \end{pmatrix} + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \right\} \tag{14.639}
$$

$$
= (n-1)\left(-33.49373\ eV - 0.16515\ eV + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \right)
$$

From Eqs. (14.637-14.639), the total energy of the $n-1$ bonds of the $C-C$ -bond MOs is:

$$
\begin{aligned}
E_{alkaneT+osc}(C-C) &= (n-1)\left(-31.63537\ eV + 2E_{T_{alkane}}\left(C-C,2sp^3\right)\right) + \bar{E}_{alkane\ osc}(C-C,\sigma) \\
&= (n-1)\begin{pmatrix} -31.63537\ eV + 2(-0.92918\ eV) \\ -0.16515\ eV + \frac{1}{2}(0.12312\ eV) \end{pmatrix} = -(n-1)33.59732\ eV
\end{aligned} \tag{14.640}
$$

where the experimental E_{vib} was used for the $\hbar\sqrt{\frac{k}{\mu}}$ term.

TOTAL BOND ENERGY OF THE $C-C$ BONDS OF CONTINUOUS-CHAIN ALKANES

Since there are two carbon atoms per bond and the number of $C-C$ bonds is $n-1$, the total bond energy of the $C-C$ bonds of C_nH_{2n+2}, $E_D(C-C)_{n-1}$, is given by $2(n-1)E\left(C,2sp^3\right)$ minus $E_{alkaneT+osc}(C-C)$ (Eq. (14.640)) where $E\left(C,2sp^3\right)$ (Eq. (14.146)) is the initial energy of each $C2sp^3$ HO of the CH_3 and CH_2 groups that bond to the $C-C$ bonds. Thus, the total dissociation energy of the $C-C$ bonds of C_nH_{2n+2}, is:

$$
\begin{aligned}
E_D(C-C)_{n-1} &= 2(n-1)\left(E\left(C,2sp^3\right)\right) - \left(E_{alakneT+osc}(C-C)\right) \\
&= 2(n-1)(-14.63489\ eV) - (n-1)(-33.59732\ eV) \\
&= (n-1)\left(2(-14.63489\ eV) - (-33.59732\ eV)\right) = (n-1)(4.32754\ eV)
\end{aligned} \tag{14.641}
$$

TOTAL ENERGY OF CONTINUOUS-CHAIN ALKANES

$E_D\left(C_nH_{2n+2}\right)$, the total bond dissociation energy of C_nH_{2n+2}, is given as the sum of the energy components due to the two methyl groups, $n-2$ methylene groups, and $n-1$ $C-C$ bonds where each energy component is given by Eqs. (14.590), (14.625), and (14.641), respectively. Thus, the total bond dissociation energy of C_nH_{2n+2} is:

$$
\begin{aligned}
E_D\left(C_nH_{2n+2}\right) &= E_D(C-C)_{n-1} + 2E_{D_{alkane}}\left({}^{12}CH_3\right) + (n-2)E_{D_{alkane}}\left({}^{12}CH_2\right) \\
&= (n-1)(4.32754\ eV) + 2(12.49186\ eV) + (n-2)(7.83016\ eV)
\end{aligned} \tag{14.642}
$$

The experimental total bond dissociation energy of C_nH_{2n+2}, $E_{D_{\exp}}\left(C_nH_{2n+2}\right)$, is given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(C_nH_{2n+2}(gas)\right)$) and the sum of the enthalpy of the formation of the reactant gaseous carbons ($\Delta H_f\left(C(gas)\right)$) and hydrogen ($\Delta H_f\left(H(gas)\right)$) atoms:

$$
\begin{aligned}
E_{D_{\exp}}\left(C_nH_{2n+2}\right) &= -\left\{\Delta H_f\left(C_nH_{2n+2}(gas)\right) - \left[n\Delta H_f\left(C(gas)\right) + (2n+2)\Delta H_f\left(H(gas)\right)\right]\right\} \\
&= -\left\{\Delta H_f\left(C_nH_{2n+2}(gas)\right) - \left[n7.42774\ eV + (2n+2)2.259353\ eV\right]\right\}
\end{aligned} \tag{14.643}
$$

where the heats of formation atomic carbon and hydrogen gas are given by [17-18]:

$$
\Delta H_f\left(C(gas)\right) = 716.68\ kJ/mole\ \left(7.42774\ eV/atom\right) \tag{14.644}
$$

$$\Delta H_f\left(H\left(gas\right)\right)=217.998\ kJ/mole\ \left(2.259353\ eV/atom\right) \tag{14.645}$$

Using the corresponding experimental $\Delta H_f\left(C_nH_{2n+2}\left(gas\right)\right)$ [18], $E_D\left(C_nH_{2n+2}\right)$ was determined for propane, butane, pentane, hexane, heptane, octane, nonane, decane, undecane, dodecane, and octadecane in the corresponding sections, and the results of the determination of the total energies are given in Table 14.1. The calculated results are based on first principles and given in closed-form, exact equations containing fundamental constants only. The agreement between the experimental and calculated results is excellent.

Using the results for C_nH_{2n+2} and the functional groups as basis sets that are linearly combined, the exact solution for the dimensional parameters, charge density functions, and energies of all molecules can be obtained. For example, one or more of the hydrogen atoms of the solution for C_nH_{2n+2} can be substituted with one or more of the previously solved functional groups or derivative functional groups to give a desired molecule. The solution is given by energy matching each group to C_nH_{2n+2}. Substitution of one or more H's of C_nH_{2n+2} with functional groups from the list of CH_3, other C_nH_{2n+2} groups, $H_2C=CH_2$, $HC\equiv CH$, F, Cl, O, OH, NH, NH_2, CN, NO, NO_2, CO, CO_2, and C_6H_6 give the solutions of branched alkanes, alkenes, and alkynes, alkyl halides, ethers, alcohols, amides, amines, nitriles, alkyl nitrosos, alkyl nitrates, aldehydes, ketones, carbolylic acids, esters, and substituted aromatics.

PROPANE (C_3H_8)

Using Eq. (14.642) with $n=3$, the total bond dissociation energy of C_3H_8 is:

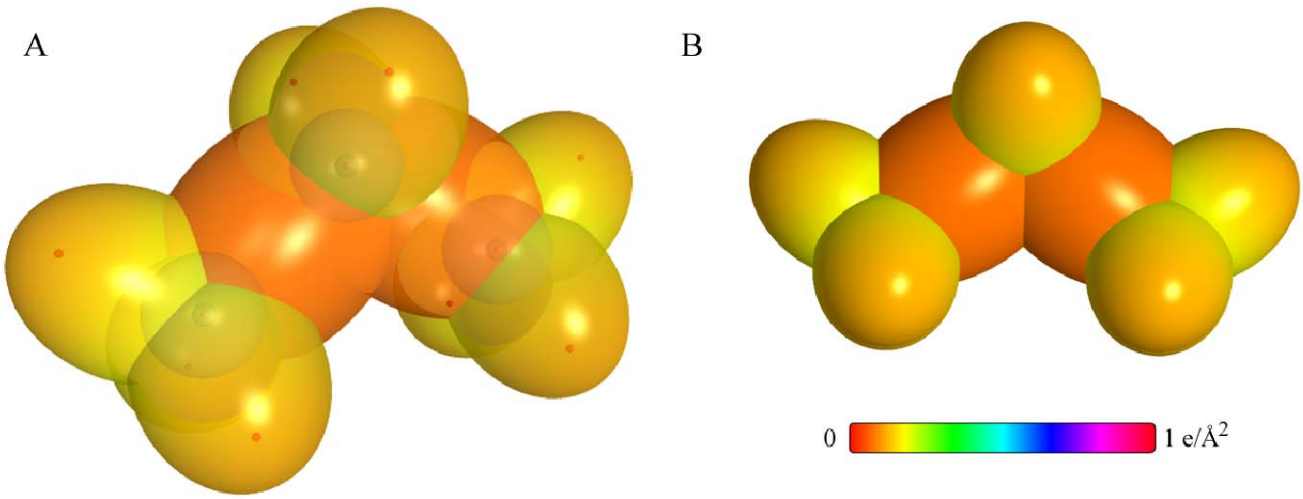
$$\begin{aligned}E_D\left(C_3H_8\right)&=E_D\left(C-C\right)_2+2E_{D_{alkane}}\left(^{12}CH_3\right)+E_{D_{alkane}}\left(^{12}CH_2\right)\\&=\left(2\right)\left(4.32754\ eV\right)+\left(2\right)\left(12.49186\ eV\right)+\left(1\right)\left(7.83016\ eV\right)=41.46896\ eV\end{aligned} \tag{14.646}$$

Using Eq. (14.643), the experimental total bond dissociation energy of C_3H_8, $E_{D_{\exp}}\left(C_3H_8\right)$, given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(C_3H_8\left(gas\right)=-1.0758\ eV\right)$) [18] and the sum of the enthalpy of the formation of the gaseous carbons ($\Delta H_f\left(C\left(gas\right)\right)$) and hydrogen ($\Delta H_f\left(H\left(gas\right)\right)$) atoms is:

$$\begin{aligned}E_{D_{\exp}}\left(C_3H_8\right)&=-\left\{\Delta H_f\left(C_3H_8\left(gas\right)\right)-\left[3\Delta H_f\left(C\left(gas\right)\right)+8\Delta H_f\left(H\left(gas\right)\right)\right]\right\}\\&=-\left\{-1.0758\ eV-\left[\left(3\right)7.42774\ eV+\left(8\right)2.259353\ eV\right]\right\}=41.434\ eV\end{aligned} \tag{14.647}$$

The charge-density of the C_3H_8 molecular orbital (MO) comprising a linear combination of two methyl groups and one methylene group is shown in Figure 14.18.

Figure 14.18. C_3H_8 MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl groups and one methylene group. (A) Color scale, translucent view of the charge-density of the $C-C$-bond and $C-H$-bond MOs and the $C_{\text{propane}}2sp^3$ HOs. Each $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{propane}2sp^3$ HOs. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C_{propane}2sp^3$ HO, the $C_{propane}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown. (B) Opaque view highlighting the $C-C$-bond MOs of the charge-density of the C_3H_8 MO.



BUTANE (C_4H_{10})

Using Eq. (14.642) with $n=4$, the total bond dissociation energy of C_4H_{10} is:

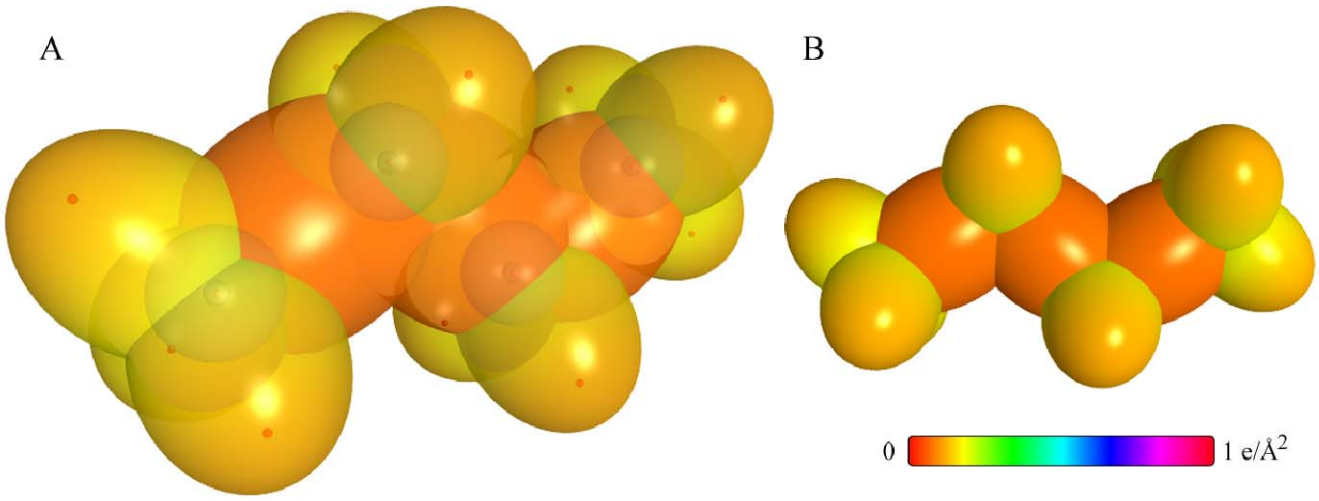
$$\begin{aligned} E_D\left(C_4H_{10}\right) &= E_D\left(C-C\right)_3 + 2E_{D_{alkane}}\left({}^{12}CH_3\right) + 2E_{D_{alkane}}\left({}^{12}CH_2\right) \\ &= (3)(4.32754\ eV) + (2)(12.49186\ eV) + (2)(7.83016\ eV) \\ &= 53.62666\ eV \end{aligned} \tag{14.648}$$

Using Eq. (14.643), the experimental total bond dissociation energy of C_4H_{10}, $E_{D_{exp}}\left(C_4H_{10}\right)$, given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(C_4H_{10}\left(gas\right)\right) = -1.3028\ eV$) [18] and the sum of the enthalpy of the formation of the gaseous carbons ($\Delta H_f\left(C\left(gas\right)\right)$) and hydrogen ($\Delta H_f\left(H\left(gas\right)\right)$) atoms is:

$$\begin{aligned} E_{D_{exp}}\left(C_4H_{10}\right) &= -\left\{\Delta H_f\left(C_4H_{10}\left(gas\right)\right) - \left[4\Delta H_f\left(C\left(gas\right)\right) + 10\Delta H_f\left(H\left(gas\right)\right)\right]\right\} \\ &= -\left\{-1.3028\ eV - \left[(4)7.42774\ eV + (10)2.259353\ eV\right]\right\} \\ &= 53.61\ eV \end{aligned} \tag{14.649}$$

The charge-density of the C_4H_{10} molecular orbital (MO) comprising a linear combination of two methyl and two methylene groups is shown in Figure 14.19.

Figure 14.19. C_4H_{10} MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and two methylene groups. (A) Color scale, translucent view of the charge-density of the $C-C$-bond and $C-H$-bond MOs and the $C_{\text{butane}}2sp^3$ HOs. Each $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{\text{butane}}2sp^3$ HOs. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C_{\text{butane}}2sp^3$ HO, the $C_{\text{butane}}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown. (B) Opaque view highlighting the $C-C$-bond MOs of the charge-density of the C_4H_{10} MO.



PENTANE (C_5H_{12})

Using Eq. (14.642) with $n=5$, the total bond dissociation energy of C_5H_{12} is:

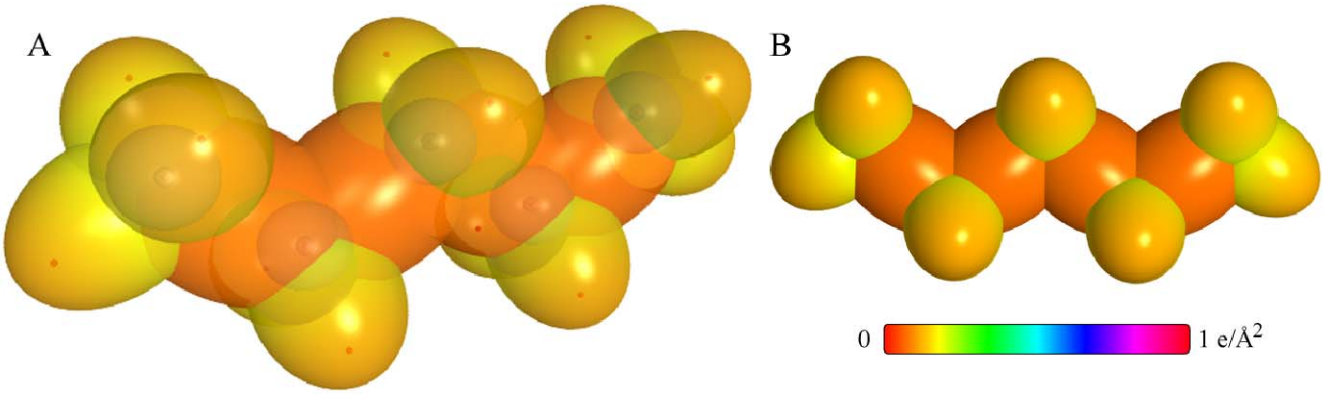
$$\begin{aligned} E_D\left(C_5H_{12}\right) &= E_D\left(C-C\right)_4 + 2E_{D_{alkane}}\left({}^{12}CH_3\right) + 3E_{D_{alkane}}\left({}^{12}CH_2\right) \\ &= (4)(4.32754\ eV) + (2)(12.49186\ eV) + (3)(7.83016\ eV) \\ &= 65.78436\ eV \end{aligned} \tag{14.650}$$

Using Eq. (14.643), the experimental total bond dissociation energy of C_5H_{12}, $E_{D_{\exp}}\left(C_5H_{12}\right)$, given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(C_5H_{12}\left(gas\right)=-1.5225\ eV\right)$) [18] and the sum of the enthalpy of the formation of the gaseous carbons ($\Delta H_f\left(C\left(gas\right)\right)$) and hydrogen ($\Delta H_f\left(H\left(gas\right)\right)$) atoms is:

$$\begin{aligned} E_{D_{\exp}}\left(C_5H_{12}\right) &= -\left\{\Delta H_f\left(C_5H_{12}\left(gas\right)\right) - \left[5\Delta H_f\left(C\left(gas\right)\right) + 12\Delta H_f\left(H\left(gas\right)\right)\right]\right\} \\ &= -\left\{-1.5225\ eV - \left[(5)7.42774\ eV + (12)2.259353\ eV\right]\right\} \\ &= 65.77\ eV \end{aligned} \tag{14.651}$$

The charge-density of the C_5H_{12} molecular orbital (MO) comprising a linear combination of two methyl and three methylene groups is shown in Figure 14.20.

Figure 14.20. C_5H_{12} MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and three methylene groups. (A) Color scale, translucent view of the charge-density of the $C-C$-bond and $C-H$-bond MOs and the $C_{\text{pentane}}2sp^3$ HOs. Each $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{\text{pentane}}2sp^3$ HOs. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C_{\text{pentane}}2sp^3$ HO, the $C_{\text{pentane}}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown. (B) Opaque view highlighting the $C-C$-bond MOs of the charge-density of the C_5H_{12} MO.



HEXANE (C_6H_{14})

Using Eq. (14.642) with $n=6$, the total bond dissociation energy of C_6H_{14} is:

$$\begin{aligned} E_D\left(C_6H_{14}\right) &= E_D\left(C-C\right)_5 + 2E_{D_{alkane}}\left({}^{12}CH_3\right) + 4E_{D_{alkane}}\left({}^{12}CH_2\right) \\ &= (5)(4.32754\ eV) + (2)(12.49186\ eV) + (4)(7.83016\ eV) \\ &= 77.94206\ eV \end{aligned} \tag{14.652}$$

Using Eq. (14.643), the experimental total bond dissociation energy of C_6H_{14}, $E_{D_{exp}}\left(C_6H_{14}\right)$, given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(C_6H_{14}\left(gas\right)=-1.7298\ eV\right)$) [18] and the sum of the enthalpy of the formation of the gaseous carbons ($\Delta H_f\left(C\left(gas\right)\right)$) and hydrogen ($\Delta H_f\left(H\left(gas\right)\right)$) atoms is:

$$\begin{aligned} E_{D_{exp}}\left(C_6H_{14}\right) &= -\left\{\Delta H_f\left(C_6H_{14}\left(gas\right)\right) - \left[6\Delta H_f\left(C\left(gas\right)\right) + 14\Delta H_f\left(H\left(gas\right)\right)\right]\right\} \\ &= -\left\{-1.7298\ eV - \left[(6)7.42774\ eV + (14)2.259353\ eV\right]\right\} \\ &= 77.93\ eV \end{aligned} \tag{14.653}$$

The charge-density of the C_6H_{14} molecular orbital (MO) comprising a linear combination of two methyl and four methylene groups is shown in Figure 14.21.

Figure 14.21. C_6H_{14} MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and four methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{\text{hexane}}2sp^3$ HOs. (B) Translucent view high-lighting the $C-C$-bond MOs of the charge-density of the C_6H_{14} MO. HEPTANE (C_7H_{16})

Using Eq. (14.642) with $n=7$, the total bond dissociation energy of C_7H_{16} is:

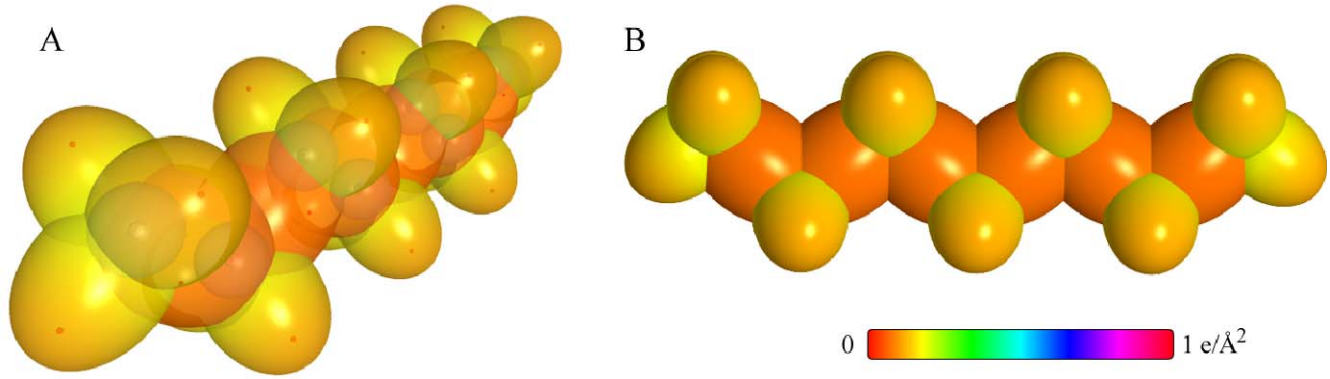
$$\begin{aligned} E_D\left(C_7H_{16}\right) &= E_D\left(C-C\right)_6 + 2E_{D_{alkane}}\left({}^{12}CH_3\right) + 5E_{D_{alkane}}\left({}^{12}CH_2\right) \\ &= (6)(4.32754\ eV) + (2)(12.49186\ eV) + (5)(7.83016\ eV) \\ &= 90.09976\ eV \end{aligned} \tag{14.654}$$

Using Eq. (14.643), the experimental total bond dissociation energy of C_7H_{16}, $E_{D_{exp}}\left(C_7H_{16}\right)$, given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(C_7H_{16}\left(gas\right)=-1.9443\ eV\right)$) [18] and the sum of the enthalpy of the formation of the gaseous carbons ($\Delta H_f\left(C\left(gas\right)\right)$) and hydrogen ($\Delta H_f\left(H\left(gas\right)\right)$) atoms is:

$$\begin{aligned} E_{D_{\exp}}\left(C_7H_{16}\right) &= -\left\{\Delta H_f\left(C_7H_{16}\left(gas\right)\right) - \left[7\Delta H_f\left(C\left(gas\right)\right) + 16\Delta H_f\left(H\left(gas\right)\right)\right]\right\} \\ &= -\left\{-1.9443\ eV - \left[(7)7.42774\ eV + (16)2.259353\ eV\right]\right\} \\ &= 90.09\ eV \end{aligned} \tag{14.655}$$

The charge-density of the C_7H_{16} MO comprising a linear combination of two methyl and five methylene groups is shown in Figure 14.22.

Figure 14.22. C_7H_{16} MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and five methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{\text{heptane}}2sp^3$ HOs. (B) Translucent view high-lighting the $C-C$-bond MOs of the charge-density of the C_7H_{16} MO. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C_{\text{heptane}}2sp^3$ HO, the $C_{\text{heptane}}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown.



OCTANE (C_8H_{18})

Using Eq. (14.642) with $n=8$, the total bond dissociation energy of C_8H_{18} is:

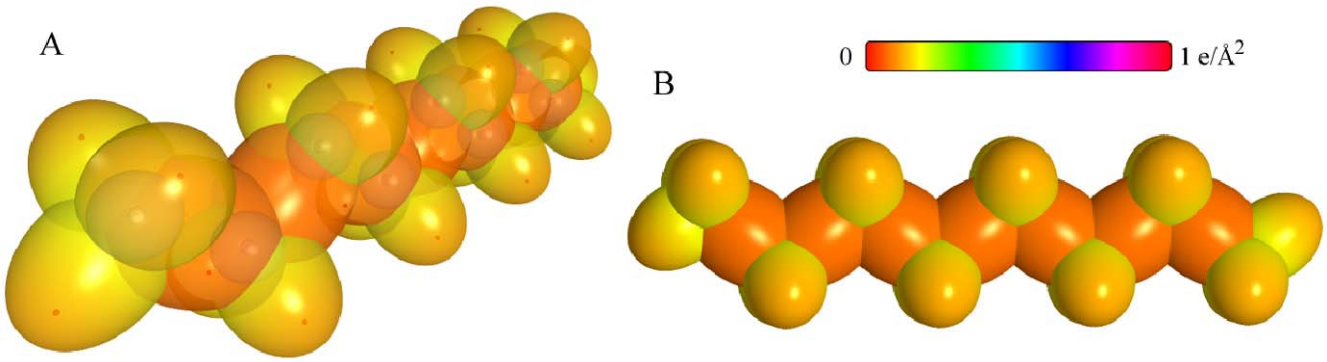
$$\begin{aligned} E_D\left(C_8H_{18}\right) &= E_D\left(C-C\right)_7 + 2E_{D_{alkane}}\left({}^{12}CH_3\right) + 6E_{D_{alkane}}\left({}^{12}CH_2\right) \\ &= (7)(4.32754\ eV) + (2)(12.49186\ eV) + (6)(7.83016\ eV) \\ &= 102.25746\ eV \end{aligned} \tag{14.656}$$

Using Eq. (14.643), the experimental total bond dissociation energy of C_8H_{18}, $E_{D_{\exp}}\left(C_8H_{18}\right)$, given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(C_8H_{18}\left(gas\right)\right) = -2.1609\ eV$) [18] and the sum of the enthalpy of the formation of the gaseous carbons ($\Delta H_f\left(C\left(gas\right)\right)$) and hydrogen ($\Delta H_f\left(H\left(gas\right)\right)$) atoms is:

$$\begin{aligned} E_{D_{\exp}}\left(C_8H_{18}\right) &= -\left\{\Delta H_f\left(C_8H_{18}\left(gas\right)\right) - \left[8\Delta H_f\left(C\left(gas\right)\right) + 18\Delta H_f\left(H\left(gas\right)\right)\right]\right\} \\ &= -\left\{-2.1609\ eV - \left[(8)7.42774\ eV + (18)2.259353\ eV\right]\right\} \\ &= 102.25\ eV \end{aligned} \tag{14.657}$$

The charge-density of the C_8H_{18} MO comprising a linear combination of two methyl and six methylene groups is shown in Figure 14.23.

Figure 14.23. C_8H_{18} MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and six methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{\text{octane}}2sp^3$ HOs. (B) Translucent view high-lighting the $C-C$-bond MOs of the charge-density of the C_8H_{18} MO. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C_{\text{octane}}2sp^3$ HO, the $C_{\text{octane}}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown.



NONANE (C_9H_{20})

Using Eq. (14.642) with $n=9$, the total bond dissociation energy of C_9H_{20} is:

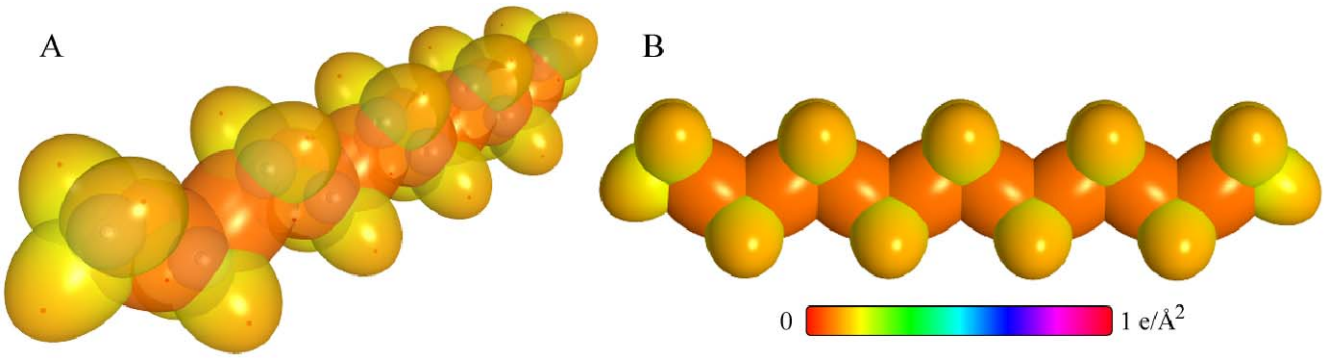
$$\begin{aligned} E_D\left(C_9H_{20}\right) &= E_D\left(C-C\right)_8 + 2E_{D_{alkane}}\left({}^{12}CH_3\right) + 7E_{D_{alkane}}\left({}^{12}CH_2\right) \\ &= (8)(4.32754\ eV) + (2)(12.49186\ eV) + (7)(7.83016\ eV) \\ &= 114.41516\ eV \end{aligned} \tag{14.658}$$

Using Eq. (14.643), the experimental total bond dissociation energy of C_9H_{20}, $E_{D_{\exp}}\left(C_9H_{20}\right)$, given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(C_9H_{20}\left(gas\right)\right) = -2.3651\ eV$) [18] and the sum of the enthalpy of the formation of the gaseous carbons ($\Delta H_f\left(C\left(gas\right)\right)$) and hydrogen ($\Delta H_f\left(H\left(gas\right)\right)$) atoms is:

$$\begin{aligned} E_{D_{\exp}}\left(C_9H_{20}\right) &= -\left\{\Delta H_f\left(C_9H_{20}\left(gas\right)\right) - \left[9\Delta H_f\left(C\left(gas\right)\right) + 20\Delta H_f\left(H\left(gas\right)\right)\right]\right\} \\ &= -\left\{-2.3651\ eV - \left[(9)7.42774\ eV + (20)2.259353\ eV\right]\right\} \\ &= 114.40\ eV \end{aligned} \tag{14.659}$$

The charge-density of the C_9H_{20} MO comprising a linear combination of two methyl and seven methylene groups is shown in Figure 14.24.

Figure 14.24. C_9H_{20} MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and seven methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{\text{nonane}}2sp^3$ HOs. (B) Translucent view high-lighting the $C-C$-bond MOs of the charge-density of the C_9H_{20} MO. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C_{\text{nonane}}2sp^3$ HO, the $C_{\text{nonane}}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown.



DECANE ($C_{10}H_{22}$)

Using Eq. (14.642) with $n=10$, the total bond dissociation energy of $C_{10}H_{22}$ is:

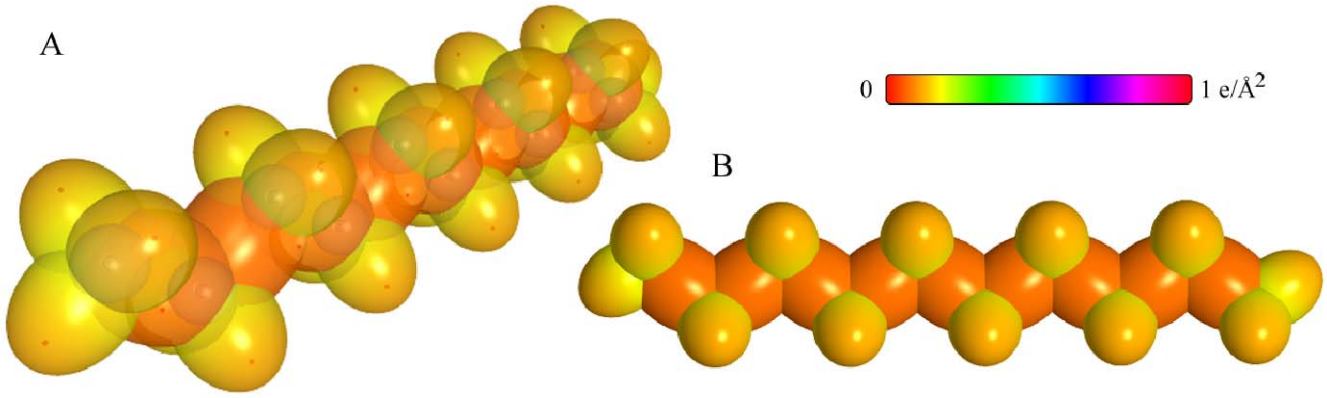
$$\begin{aligned} E_D\left(C_{10}H_{22}\right) &= E_D\left(C-C\right)_9 + 2E_{D_{alkane}}\left({}^{12}CH_3\right) + 8E_{D_{alkane}}\left({}^{12}CH_2\right) \\ &= (9)(4.32754\ eV) + (2)(12.49186\ eV) + (8)(7.83016\ eV) \\ &= 126.57286\ eV \end{aligned} \tag{14.660}$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{10}H_{22}$, $E_{D_{\exp}}\left(C_{10}H_{22}\right)$, given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(C_{10}H_{22}\left(gas\right)\right) = -2.5858\ eV$) [18] and the sum of the enthalpy of the formation of the gaseous carbons ($\Delta H_f\left(C\left(gas\right)\right)$) and hydrogen ($\Delta H_f\left(H\left(gas\right)\right)$) atoms is:

$$\begin{aligned} E_{D_{\exp}}\left(C_{10}H_{22}\right) &= -\left\{\Delta H_f\left(C_{10}H_{22}\left(gas\right)\right) - \left[10\Delta H_f\left(C\left(gas\right)\right) + 22\Delta H_f\left(H\left(gas\right)\right)\right]\right\} \\ &= -\left\{-2.5858\ eV - \left[(10)7.42774\ eV + (22)2.259353\ eV\right]\right\} \\ &= 126.57\ eV \end{aligned} \tag{14.661}$$

The charge-density of the $C_{10}H_{22}$ molecular orbital (MO) comprising a linear combination of two methyl and eight methylene groups is shown in Figure 14.25.

Figure 14.25. $C_{10}H_{22}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and eight methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{\text{decane}}2sp^3$ HOs. (B) Translucent view high-lighting the $C-C$-bond MOs of the charge-density of the $C_{10}H_{22}$ MO. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C_{\text{decane}}2sp^3$ HO, the $C_{\text{decane}}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown.



UNDECANE ($C_{11}H_{24}$)

Using Eq. (14.642) with $n=11$, the total bond dissociation energy of $C_{11}H_{24}$ is:

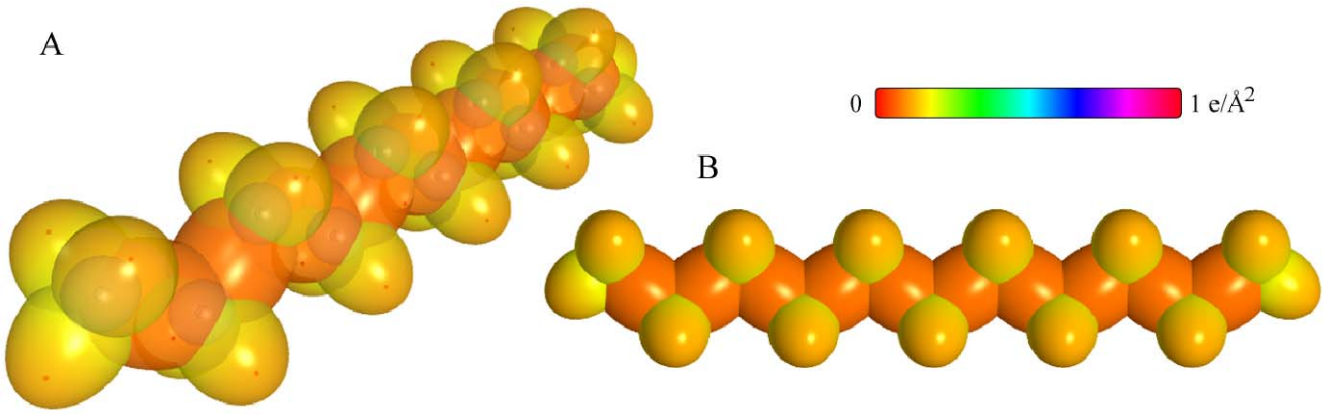
$$\begin{aligned} E_D\left(C_{11}H_{24}\right) &= E_D\left(C-C\right)_{10} + 2E_{D_{alkane}}\left({}^{12}CH_3\right) + 9E_{D_{alkane}}\left({}^{12}CH_2\right) \\ &= (10)(4.32754\ eV) + (2)(12.49186\ eV) + (9)(7.83016\ eV) \\ &= 138.73056\ eV \end{aligned} \tag{14.662}$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{11}H_{24}$, $E_{D_{\exp}}\left(C_{11}H_{24}\right)$, given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(C_{11}H_{24}\left(gas\right)\right) = -2.8066\ eV$) [18] and the sum of the enthalpy of the formation of the gaseous carbons ($\Delta H_f\left(C\left(gas\right)\right)$) and hydrogen ($\Delta H_f\left(H\left(gas\right)\right)$) atoms is:

$$\begin{aligned} E_{D_{\exp}}\left(C_{11}H_{24}\right) &= -\left\{\Delta H_f\left(C_{11}H_{24}\left(gas\right)\right) - \left[11\Delta H_f\left(C\left(gas\right)\right) + 24\Delta H_f\left(H\left(gas\right)\right)\right]\right\} \\ &= -\left\{-2.8066\ eV - \left[(11)7.42774\ eV + (24)2.259353\ eV\right]\right\} \\ &= 138.736\ eV \end{aligned} \tag{14.663}$$

The charge-density of the $C_{11}H_{24}$ MO comprising a linear combination of two methyl and nine methylene groups is shown in Figure 14.26.

Figure 14.26. $C_{11}H_{24}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and nine methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{\text{undecane}}2sp^3$ HOs. (B) Translucent view high-lighting the $C-C$-bond MOs of the charge-density of the $C_{11}H_{24}$ MO. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C_{\text{undecane}}2sp^3$ HO, the $C_{\text{undecane}}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown.



DODECANE ($C_{12}H_{26}$)

Using Eq. (14.642) with $n=12$, the total bond dissociation energy of $C_{12}H_{26}$ is:

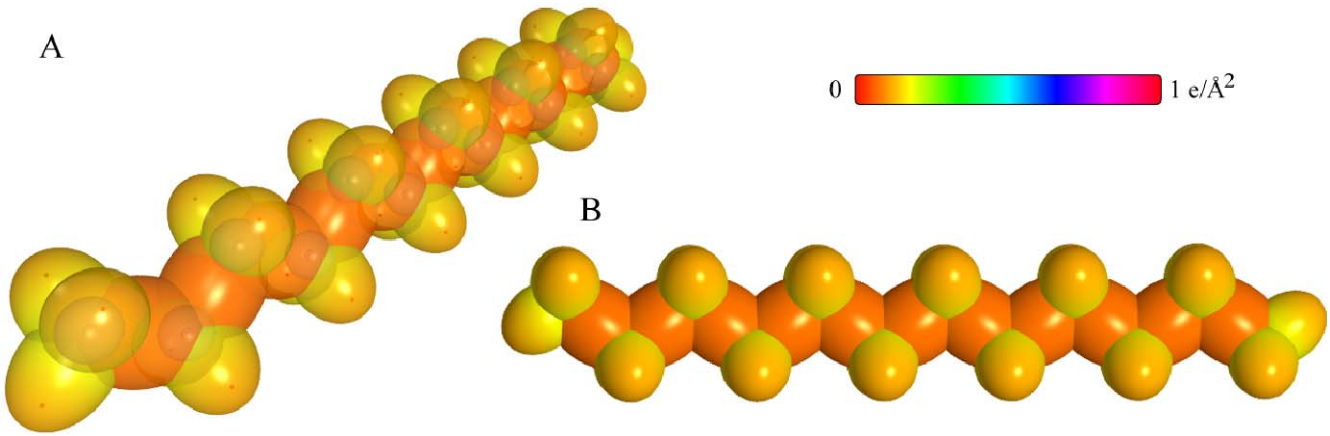
$$\begin{aligned} E_D\left(C_{12}H_{26}\right) &= E_D\left(C-C\right)_{11} + 2E_{D_{alkane}}\left({}^{12}CH_3\right) + 10E_{D_{alkane}}\left({}^{12}CH_2\right) \\ &= (11)(4.32754\ eV) + (2)(12.49186\ eV) + (10)(7.83016\ eV) \\ &= 150.88826\ eV \end{aligned} \tag{14.664}$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{12}H_{26}$, $E_{D_{\exp}}\left(C_{12}H_{26}\right)$, given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(C_{12}H_{26}\left(gas\right)\right) = -2.9994\ eV$) [18] and the sum of the enthalpy of the formation of the gaseous carbons ($\Delta H_f\left(C\left(gas\right)\right)$) and hydrogen ($\Delta H_f\left(H\left(gas\right)\right)$) atoms is:

$$\begin{aligned} E_{D_{\exp}}\left(C_{12}H_{26}\right) &= -\left\{\Delta H_f\left(C_{12}H_{26}\left(gas\right)\right) - \left[12\Delta H_f\left(C\left(gas\right)\right) + 26\Delta H_f\left(H\left(gas\right)\right)\right]\right\} \\ &= -\left\{-2.9994\ eV - \left[(12)7.42774\ eV + (26)2.259353\ eV\right]\right\} \\ &= 150.88\ eV \end{aligned} \tag{14.665}$$

The charge-density of the $C_{12}H_{26}$ MO comprising a linear combination of two methyl and ten methylene groups is shown in Figure 14.27.

Figure 14.27. $C_{12}H_{26}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and ten methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{\text{dodecane}}2sp^3$ HOs. (B) Translucent view high-lighting the $C-C$-bond MOs of the charge-density of the $C_{12}H_{26}$ MO. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C_{\text{dodecane}}2sp^3$ HO, the $C_{\text{dodecane}}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown.



OCTADECANE ($C_{18}H_{38}$)

Using Eq. (14.642) with $n=18$, the total bond dissociation energy of $C_{18}H_{38}$ is:

$$\begin{aligned} E_D\left(C_{18}H_{38}\right) &= E_D\left(C-C\right)_{17} + 2E_{D_{alkane}}\left({}^{12}CH_3\right) + 16E_{D_{alkane}}\left({}^{12}CH_2\right) \\ &= (17)(4.32754\ eV) + (2)(12.49186\ eV) + (16)(7.83016\ eV) \\ &= 223.83446\ eV \end{aligned} \tag{14.666}$$

Using Eq. (14.643), the experimental total bond dissociation energy of $C_{18}H_{38}$, $E_{D_{\exp}}\left(C_{18}H_{38}\right)$, given by the negative difference between the enthalpy of its formation ($\Delta H_f\left(C_{18}H_{38}\left(gas\right)\right) = -4.2970\ eV$) [18] and the sum of the enthalpy of the formation of the gaseous carbons ($\Delta H_f\left(C\left(gas\right)\right)$) and hydrogen ($\Delta H_f\left(H\left(gas\right)\right)$) atoms is:

$$\begin{aligned} E_{D_{\exp}}\left(C_{18}H_{38}\right) &= -\left\{\Delta H_f\left(C_{18}H_{38}\left(gas\right)\right) - \left[18\Delta H_f\left(C\left(gas\right)\right) + 38\Delta H_f\left(H\left(gas\right)\right)\right]\right\} \\ &= -\left\{-4.2970\ eV - \left[(18)7.42774\ eV + (38)2.259353\ eV\right]\right\} \\ &= 223.85\ eV \end{aligned} \tag{14.667}$$

The charge-density of the $C_{18}H_{38}$ molecular orbital (MO) comprising a linear combination of two methyl and sixteen methylene groups is shown in Figure 14.28.

Figure 14.28. $C_{18}H_{38}$ MO comprising a linear combination of $C-H$-bond MOs and $C-C$-bond MOs of the two methyl and sixteen methylene groups. (A) Opaque view of the charge-density of the $C-C$-bond and $C-H$-bond MOs. Each $C-C$-bond MO comprises a H_2-type ellipsoidal MO bridging two $C_{\text{octadecane}}2sp^3$ HOs. (B) Translucent view high-lighting the $C-C$-bond MOs of the charge-density of the $C_{18}H_{38}$ MO. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C_{\text{octadecane}}2sp^3$ HO, the $C_{\text{octadecane}}2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown.

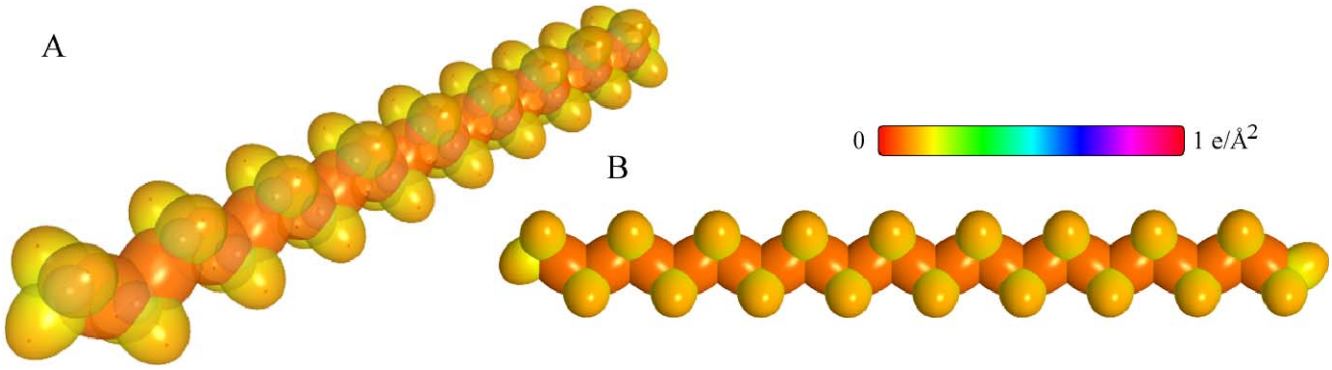


Table 14.1. The calculated and experimental bond parameters of CO_2, NO_2, CH_3CH_3, CH_2CH_2, $CHCH$, benzene, propane, butane, pentane, hexane, heptane, octane, nonane, decane, undecane, dodecane, and octadecane.

Parameter	Calculated	Experimental	Ref. for Exp.
CO_2 Bond Energy	5.49553 eV	5.51577 eV	7
CO_2 Bond Length	1.1616 Å	1.1600 Å	3
NO_2 Bond Energy	3.1532 eV	3.161 eV	7
NO_2 Bond Length	1.1872 Å	1.193 Å	3
NO_2 Bond Angle	131.012°	134.1°	3
H_3C-CH_3 Bond Energy	3.90245 eV	3.8969 eV	7
H_3C-CH_3 Bond Length	1.53635 Å	1.5351 Å	3
$H-CH_2CH_3$ Bond Length	1.10822 Å	1.0940 Å	3
Ethane $H-C-H$ Bond Angle	107.44°	107.4°	8
Ethane $C-C-H$ Bond Angle	111.44°	111.17°	3
$H_2C=CH_2$ Bond Energy	7.55681 eV	7.597 eV	7
$H_2C=CH_2$ Bond Length	1.3405 Å	1.339 Å	3
$H-CHCH_2$ Bond Length	1.0826 Å	1.087 Å	3
Ethylene $H-C-H$ Bond Angle	116.31°	116.6°	11
Ethylene $C=C-H$ Bond Angle	121.85°	121.7°	11
$HC\equiv CH$ Bond Energy	10.07212 eV	10.0014 eV	7
$HC\equiv CH$ Bond Length	1.2007 Å	1.203 Å	3
$H-CCH$ Bond Length	1.0538 Å	1.060 Å	3
Acetylene $C\equiv C-H$ Bond Angle	180°	180°	6
C_6H_6 Total Bond Energy	57.2601 eV	57.26 eV	17-18
Benzene $C=C$ Bond Length	1.3914 Å	1.399 Å	3
$H-C_6H_5$ Bond Length	1.0933 Å	1.101 Å	3
C_6H_6 $C=C=C$ Bond Angle	120°	120°	13-15
C_6H_6 $C=C-H$ Bond Angle	120°	120°	13-15
C_3H_8 Total Bond Energy	41.46896 eV	41.434 eV	17-18
Propane $C-C$ Bond Length	1.5428 Å	1.532 Å	3
Propane $C-H$ Bond Length	1.1097 Å	1.107 Å	3
Alkane $H-C-H$ Bond Angle	109.50°	109.3°	19
Alkane $C-C-H$ Bond Angle	109.44°	109.3°	19
C_4H_{10} Total Bond Energy	53.62666 eV	53.61 eV	17-18
Butane $C-C$ Bond Length	1.5428 Å	1.531 Å	3
Butane $C-H$ Bond Length	1.11713 Å	1.117 Å	3
C_5H_{12} Total Bond Energy	65.78436 eV	65.77 eV	17-18
C_6H_{14} Total Bond Energy	77.94206 eV	77.93 eV	17-18
C_7H_{16} Total Bond Energy	90.09976 eV	90.09 eV	17-18
C_8H_{18} Total Bond Energy	102.25746 eV	102.25 eV	17-18
C_9H_{20} Total Bond Energy	114.41516 eV	114.40 eV	17-18
$C_{10}H_{22}$ Total Bond Energy	126.57286 eV	126.57 eV	17-18
$C_{11}H_{24}$ Total Bond Energy	138.73056 eV	138.736 eV	17-18
$C_{12}H_{26}$ Total Bond Energy	150.88826 eV	150.88 eV	17-18
$C_{18}H_{38}$ Total Bond Energy	223.83446 eV	223.85 eV	17-18

Chapter 15

ORGANIC MOLECULAR FUNCTIONAL GROUPS AND MOLECULES

DERIVATION OF THE GENERAL GEOMETRICAL AND ENERGY EQUATIONS OF ORGANIC CHEMISTRY

Organic molecules comprising an arbitrary number of atoms can be solved using similar principles and procedures as those used to solve alkanes of arbitrary length. Alkanes can be considered to be comprised of the functional groups of CH_3, CH_2, and $C-C$. These groups with the corresponding geometrical parameters and energies can be added as a linear sum to give the solution of any straight chain alkane as shown in the Continuous-Chain Alkanes section. Similarly, the geometrical parameters and energies of all functional groups such as alkanes, branched alkanes, alkenes, branched alkenes, alkynes, alkyl fluorides, alkyl chlorides, alkyl bromides, alkyl iodides, alkene halides, primary alcohols, secondary alcohols, tertiary alcohols, ethers, primary amines, secondary amines, tertiary amines, aldehydes, ketones, carboxylic acids, carboxylic esters, amides, N-alkyl amides, N,N-dialkyl amides, urea, acid halides, acid anhydrides, nitriles, thiols, sulfides, disulfides, sulfoxides, sulfones, sulfites, sulfates, nitro alkanes, nitrites, nitrates, conjugated polyenes, aromatics, heterocyclic aromatics, substituted aromatics, and others can be solved. The functional-group solutions can be made into a linear superposition and sum, respectively, to give the solution of any organic molecule. The solutions of the functional groups can be conveniently obtained by using generalized forms of the geometrical and energy equations. The total bond energies of exemplary organic molecules calculated using the functional group composition and the corresponding energies derived in the following sections compared to the experimental values are given in Tables 15.410.1–15.410.43.

Consider the case wherein at least two atomic orbitals hybridize as a linear combination of electrons at the same energy in order to achieve a bond at an energy minimum, and the sharing of electrons between two or more such orbitals to form a MO permits the participating hybridized orbitals to decrease in energy through a decrease in the radius of one or more of the participating orbitals. The force-generalized constant k' of a H_2-type ellipsoidal MO due to the equivalent of two point charges at the foci is given by:

$$k' = \frac{C_1 C_2 2e^2}{4\pi\varepsilon_0} \tag{15.1}$$

where C_1 is the fraction of the H_2-type ellipsoidal MO basis function of a chemical bond of the molecule or molecular ion which is 0.75 (Eq. (13.59)) in the case of H bonding to a central atom and 0.5 (Eq. (14.152)) otherwise, and C_2 is the factor that results in an equipotential energy match of the participating at least two molecular or atomic orbitals of the chemical bond. From Eqs. (13.58-13.63), the distance from the origin of the MO to each focus c' is given by:

$$c' = a\sqrt{\frac{\hbar^2 4\pi\varepsilon_0}{m_e e^2 2C_1 C_2 a}} = \sqrt{\frac{aa_0}{2C_1 C_2}} \tag{15.2}$$

The internuclear distance is

$$2c' = 2\sqrt{\frac{aa_0}{2C_1 C_2}} \tag{15.3}$$

The length of the semiminor axis of the prolate spheroidal MO $b = c$ is given by:

$$b = \sqrt{a^2 - c'^2} \tag{15.4}$$

And, the eccentricity, e, is

$$e = \frac{c'}{a} \tag{15.5}$$

From Eqs. (11.207-11.212), the potential energy of the two electrons in the central field of the nuclei at the foci is:

$$V_e = n_1 c_1 c_2 \frac{-2e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} \ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} \tag{15.6}$$

The potential energy of the two nuclei is:

$$V_p = n_1 \frac{e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}} \tag{15.7}$$

The kinetic energy of the electrons is

$$T = n_1 c_1 c_2 \frac{\hbar^2}{2m_e a\sqrt{a^2-b^2}} \ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} \tag{15.8}$$

And, the energy, V_m, of the magnetic force between the electrons is:

$$V_m = n_1 c_1 c_2 \frac{-\hbar^2}{4m_e a\sqrt{a^2-b^2}} \ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} \tag{15.9}$$

The total energy of the H_2-type prolate spheroidal MO, $E_T(_{H_2MO})$, is given by the sum of the energy terms:

$$E_T(_{H_2MO}) = V_e + T + V_m + V_p \tag{15.10}$$

$$E_T(_{H_2MO}) = -\frac{n_1 e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\left[c_1 c_2\left(2-\frac{a_0}{a}\right)\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} - 1\right] = -\frac{n_1 e^2}{8\pi\varepsilon_0 c'}\left[c_1 c_2\left(2-\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'} - 1\right] \tag{15.11}$$

where n_1 is the number of equivalent bonds of the MO and applies in the case of functional groups. In the case of independent MOs not in contact with the bonding atoms, the terms based on charge are multiplied by c_{BO}, the bond-order factor. It is 1 for a single bond, 4 for an independent double bond as in the case of the CO_2 and NO_2 molecules, and 9 for an independent triplet bond. Then, the kinetic energy term is multiplied by c'_{BO} which is 1 for a single bond, 2 for a double bond, and 9/2 for a triple bond. c_1 is the fraction of the H_2-type ellipsoidal MO basis function of an MO which is 0.75 (Eqs. (13.67-13.73)) in the case of H bonding to an unhybridized central atom and 1 otherwise, and c_2 is the factor that results in an equipotential energy match of the participating MO and at least two atomic orbitals of the chemical bond. Specifically, to meet the equipotential condition and energy matching conditions for the union of the H_2-type-ellipsoidal-MO and the HOs or AOs of the bonding atoms, the factor c_2 of a H_2-type ellipsoidal MO may given by (i) one, (ii) the ratio of the Coulombic or valence energy of the AO or HO of at least one atom of the bond and 13.605804 eV, the Coulombic energy between the electron and proton of H, (iii) the ratio of the valence energy of the AO or HO of one atom and the Coulombic energy of another, (iv) the ratio of the valence energies of the AOs or HOs of two atoms, (v) the ratio of two c_2 factors corresponding to any of cases (ii)-(iv), and (vi) the product of two different c_2 factors corresponding to any of the cases (i)-(v). Specific examples of the factor c_2 of a H_2-type ellipsoidal MO given in previous sections are:

0.936127, the ratio of the ionization energy of N 14.53414 eV and 13.605804 eV, the Coulombic energy between the electron and proton of H;

0.91771, the ratio of 14.82575 eV, $-E_{Coulomb}\left(C, 2sp^3\right)$, and 13.605804 eV;

0.87495, the ratio of 15.55033 eV, $-E_{Coulomb}\left(C_{ethane}, 2sp^3\right)$, and 13.605804 eV;

0.85252, the ratio of 15.95955 eV, $-E_{Coulomb}\left(C_{ethylene}, 2sp^3\right)$, and 13.605804 eV;

0.85252, the ratio of 15.95955 eV, $-E_{Coulomb}\left(C_{benzene}, 2sp^3\right)$, and 13.605804 eV, and

0.86359, the ratio of 15.55033 eV, $-E_{Coulomb}\left(C_{alkane}, 2sp^3\right)$, and 13.605804 eV.

In the generalization of the hybridization of at least two atomic-orbital shells to form a shell of hybrid orbitals, the hybridized shell comprises a linear combination of the electrons of the atomic-orbital shells. The radius of the hybridized shell is calculated from the total Coulombic energy equation by considering that the central field decreases by an integer for each successive electron of the shell and that the total energy of the shell is equal to the total Coulombic energy of the initial AO electrons. The total energy $E_T\left(atom, msp^3\right)$ (m is the integer of the valence shell) of the AO electrons and the hybridized shell is given by the sum of energies of successive ions of the atom over the n electrons comprising total electrons of the at least one AO shell.

$$E_T\left(atom, msp^3\right) = -\sum_{m=1}^{n} IP_m \tag{15.12}$$

where IP_m is the m th ionization energy (positive) of the atom. The radius r_{msp^3} of the hybridized shell is given by:

$$r_{msp^3} = \sum_{q=Z-n}^{Z-1} \frac{-(Z-q)e^2}{8\pi\varepsilon_0 E_T\left(atom, msp^3\right)} \tag{15.13}$$

Then, the Coulombic energy $E_{Coulomb}\left(atom, msp^3\right)$ of the outer electron of the *atom* msp^3 shell is given by:

$$E_{Coulomb}\left(atom, msp^3\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{msp^3}} \tag{15.14}$$

In the case that during hybridization at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E(magnetic)$ at the initial radius r of the AO electron:

$$E(magnetic) = \frac{2\pi\mu_0 e^2\hbar^2}{m_e^2 r^3} = \frac{8\pi\mu_0\mu_B^2}{r^3} \tag{15.15}$$

Then, the energy $E\left(atom, msp^3\right)$ of the outer electron of the *atom* msp^3 shell is given by the sum of $E_{Coulomb}\left(atom, msp^3\right)$ and $E(magnetic)$:

$$E\left(atom, msp^3\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{msp^3}} + \frac{2\pi\mu_0 e^2\hbar^2}{m_e^2 r^3} \tag{15.16}$$

Consider next that the at least two atomic orbitals hybridize as a linear combination of electrons at the same energy in order to achieve a bond at an energy minimum with another atomic orbital or hybridized orbital. As a further generalization of the basis of the stability of the MO, the sharing of electrons between two or more such hybridized orbitals to form a MO permits the participating hybridized orbitals to decrease in energy through a decrease in the radius of one or more of the participating orbitals. In this case, the total energy of the hybridized orbitals is given by the sum of $E\left(atom, msp^3\right)$ and the next energies of successive ions of the atom over the n electrons comprising the total electrons of the at least two initial AO shells. Here, $E\left(atom, msp^3\right)$ is the sum of the first ionization energy of the atom and the hybridization energy. An example of $E\left(atom, msp^3\right)$ for $E\left(C, 2sp^3\right)$ is given in Eq. (14.503) where the sum of the negative of the first ionization energy of C, $-11.27671\ eV$, plus the hybridization energy to form the $C2sp^3$ shell given by Eq. (14.146) is $E\left(C, 2sp^3\right) = -14.63489\ eV$.

Thus, the sharing of electrons between two *atom* msp^3 HOs to form an atom-atom-bond MO permits each participating hybridized orbital to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each *atom* msp^3 HO donates an excess of 25% per bond of its electron density to the atom-atom-bond MO to form an energy minimum wherein the atom-atom bond comprises one of a single, double, or triple bond. In each case, the radius of the hybridized shell is calculated from the Coulombic energy equation by considering that the central field decreases by an integer for each successive electron of the shell and the total energy of the shell is equal to the total Coulombic energy of the initial AO electrons plus the hybridization energy. The total energy $E_T\left(mol.atom, msp^3\right)$ (m is the integer of the valence shell) of the HO electrons is given by the sum of energies of successive ions of the atom over the n electrons comprising total electrons of the at least one initial AO shell and the hybridization energy:

$$E_T\left(mol.atom, msp^3\right) = E\left(atom, msp^3\right) - \sum_{m=2}^{n} IP_m \tag{15.17}$$

where IP_m is the m th ionization energy (positive) of the atom and the sum of $-IP_1$ plus the hybridization energy is $E\left(atom, msp^3\right)$. Thus, the radius r_{msp^3} of the hybridized shell due to its donation of a total charge $-Qe$ to the corresponding MO is given by:

$$r_{msp^3} = \left(\sum_{q=Z-n}^{Z-1} (Z-q) - Q\right)\frac{-e^2}{8\pi\varepsilon_0 E_T\left(mol.atom, msp^3\right)} = \left(\sum_{q=Z-n}^{Z-1} (Z-q) - s(0.25)\right)\frac{-e^2}{8\pi\varepsilon_0 E_T\left(mol.atom, msp^3\right)} \tag{15.18}$$

where $-e$ is the fundamental electron charge and $s = 1, 2, 3$ for a single, double, and triple bond, respectively. The Coulombic energy $E_{Coulomb}\left(mol.atom, msp^3\right)$ of the outer electron of the *atom* msp^3 shell is given by:

$$E_{Coulomb}\left(mol.atom, msp^3\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{msp^3}} \tag{15.19}$$

In the case that during hybridization at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E(magnetic)$ at the initial radius r of the AO electron given by Eq. (15.15). Then, the energy $E\left(mol.atom, msp^3\right)$ of the outer electron of the *atom* msp^3 shell is given by the sum of $E_{Coulomb}\left(mol.atom, msp^3\right)$ and $E(magnetic)$:

$$E\left(mol.atom, msp^3\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{msp^3}} + \frac{2\pi\mu_0 e^2\hbar^2}{m_e^2 r^3} \tag{15.20}$$

$E_T\left(atom-atom, msp^3\right)$, the energy change of each *atom* msp^3 shell with the formation of the atom-atom-bond MO is given by: the difference between $E\left(mol.atom, msp^3\right)$ and $E\left(atom, msp^3\right)$:

$$E_T\left(atom-atom, msp^3\right) = E\left(mol.atom, msp^3\right) - E\left(atom, msp^3\right) \tag{15.21}$$

As examples from prior sections, $E_{Coulomb}\left(mol.atom, msp^3\right)$ is one of:

$E_{Coulomb}\left(C_{ethylene}, 2sp^3\right)$, $E_{Coulomb}\left(C_{ethane}, 2sp^3\right)$, $E_{Coulomb}\left(C_{acetylene}, 2sp^3\right)$, and $E_{Coulomb}\left(C_{alkane}, 2sp^3\right)$;

$E_{Coulomb}\left(atom, msp^3\right)$ is one of $E_{Coulomb}\left(C, 2sp^3\right)$ and $E_{Coulomb}\left(Cl, 3sp^3\right)$;

$E\left(mol.atom, msp^3\right)$ is one of $E\left(C_{ethylene}, 2sp^3\right)$, $E\left(C_{ethane}, 2sp^3\right)$, $E\left(C_{acetylene}, 2sp^3\right)$ and $E\left(C_{alkane}, 2sp^3\right)$;

$E\left(atom, msp^3\right)$ is one of $E\left(C, 2sp^3\right)$ and $E\left(Cl, 3sp^3\right)$;

$E_T\left(atom-atom, msp^3\right)$ is one of $E\left(C-C, 2sp^3\right)$, $E\left(C=C, 2sp^3\right)$, and $E\left(C\equiv C, 2sp^3\right)$;

atom msp^3 is one of $C2sp^3$, and $Cl3sp^3$

$E_T\left(atom-atom(s_1), msp^3\right)$ is $E_T\left(C-C, 2sp^3\right)$ and $E_T\left(atom-atom(s_2), msp^3\right)$ is $E_T\left(C=C, 2sp^3\right)$, and

r_{msp^3} is one of r_{C2sp^3}, $r_{ethane2sp^3}$, $r_{ethylene2sp^3}$, $r_{acetylene2sp^3}$, $r_{alkane2sp^3}$, and r_{Cl3sp^3}.

In the case of the $C2sp^3$ HO, the initial parameters (Eqs. (14.142-14.146)) are:

$$r_{2sp^3} = \sum_{n=2}^{5} \frac{(Z-n)e^2}{8\pi\varepsilon_0\left(e148.25751\ eV\right)} = \frac{10e^2}{8\pi\varepsilon_0\left(e148.25751\ eV\right)} = 0.91771a_0 \tag{15.22}$$

$$E_{Coulomb}\left(C, 2sp^3\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{2sp^3}} = \frac{-e^2}{8\pi\varepsilon_0 0.91771a_0} = -14.82575\ eV \tag{15.23}$$

$$E(magnetic) = \frac{2\pi\mu_0 e^2\hbar^2}{m_e^2\left(r_3\right)^3} = \frac{8\pi\mu_0\mu_B^2}{\left(0.84317a_0\right)^3} = 0.19086\ eV \tag{15.24}$$

$$E\left(C, 2sp^3\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{2sp^3}} + \frac{2\pi\mu_0 e^2\hbar^2}{m_e^2\left(r_3\right)^3} = -14.82575\ eV + 0.19086\ eV = -14.63489\ eV \tag{15.25}$$

In Eq. (15.18),

$$\sum_{q=Z-n}^{Z-1}(Z-q) = 10 \tag{15.26}$$

Eqs. (14.147) and (15.17) gives:

$$E_T\left(mol.atom, msp^3\right) = E_T\left(C_{ethane}, 2sp^3\right) = -151.61569\ eV \tag{15.27}$$

Using Eqs. (15.18-15.28), the final values of r_{C2sp^3}, $E_{Coulomb}\left(C2sp^3\right)$, and $E\left(C2sp^3\right)$, and the resulting $E_T\left(C\overset{BO}{-}C, C2sp^3\right)$ of the MO due to charge donation from the HO to the MO where $C\overset{BO}{-}C$ refers to the bond order of the carbon-carbon bond for different values of the parameter s are given in Table 15.1.

Table 15.1. The final values of r_{C2sp^3}, $E_{Coulomb}(C2sp^3)$, and $E(C2sp^3)$ and the resulting $E_T(C\overset{BO}{-}C,C2sp^3)$ of the MO due to charge donation from the HO to the MO where $C\overset{BO}{-}C$ refers to the bond order of the carbon-carbon bond.

MO Bond Order (BO)	s_1	s_2	$r_{C2sp^3}(a_0)$ Final	$E_{Coulomb}\left(C2sp^3\right)$ (eV) Final	$E\left(C2sp^3\right)$ (eV) Final	$E_T\left(C\overset{BO}{-}C,C2sp^3\right)$ (eV)
I	1	0	0.87495	-15.55033	-15.35946	-0.72457
II	2	0	0.85252	-15.95955	-15.76868	-1.13379
III	3	0	0.83008	-16.39089	-16.20002	-1.56513
IV	4	0	0.80765	-16.84619	-16.65532	-2.02043

In another generalized case of the basis of forming a minimum-energy bond with the constraint that it must meet the energy matching condition for all MOs at all HOs or AOs, the energy $E\left(mol.atom,msp^3\right)$ of the outer electron of the *atom* msp^3 shell of each bonding atom must be the average of $E\left(mol.atom,msp^3\right)$ for two different values of s:

$$E\left(mol.atom,msp^3\right)=\frac{E\left(mol.atom\left(s_1\right),msp^3\right)+E\left(mol.atom\left(s_2\right),msp^3\right)}{2} \tag{15.28}$$

In this case, $E_T\left(atom-atom,msp^3\right)$, the energy change of each *atom* msp^3 shell with the formation of each atom-atom-bond MO, is average for two different values of s:

$$E_T\left(atom-atom,msp^3\right)=\frac{E_T\left(atom-atom\left(s_1\right),msp^3\right)+E_T\left(atom-atom\left(s_2\right),msp^3\right)}{2} \tag{15.29}$$

Consider an aromatic molecule such as benzene given in the Benzene Molecule section. Each $C=C$ double bond comprises a linear combination of a factor of 0.75 of four paired electrons (three electrons) from two sets of two $C2sp^3$ HOs of the participating carbon atoms. Each $C-H$ bond of CH having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of 75% H_2-type ellipsoidal MO and 25% $C2sp^3$ HO as given by Eq. (13.439). However, $E_T\left(atom-atom,msp^3\right)$ of the $C-H$-bond MO is given by $0.5E_T\left(C=C,2sp^3\right)$ (Eq. (14.247)) corresponding to one half of a double bond that matches the condition for a single-bond order for $C-H$ that is lowered in energy due to the aromatic character of the bond.

A further general possibility is that a minimum-energy bond is achieved with satisfaction of the potential, kinetic, and orbital energy relationships by the formation of an MO comprising an allowed multiple of a linear combination of H_2-type ellipsoidal MOs and corresponding HOs or AOs that contribute a corresponding allowed multiple (e.g. 0.5, 0.75, 1) of the bond order given in Table 15.1. For example, the alkane MO given in the Continuous-Chain Alkanes section comprises a linear combination of factors of 0.5 of a single bond and 0.5 of a double bond.

Consider a first MO and its HOs comprising a linear combination of bond orders and a second MO that shares a HO with the first. In addition to the mutual HO, the second MO comprises another AO or HO having a single bond order or a mixed bond order. Then, in order for the two MOs to be energy matched, the bond order of the second MO and its HOs or its HO and AO is a linear combination of the terms corresponding to the bond order of the mutual HO and the bond order of the independent HO or AO. Then, in general, $E_T\left(atom-atom,msp^3\right)$, the energy change of each *atom* msp^3 shell with the formation of each atom-atom-bond MO, is a weighted linear sum for different values of s that matches the energy of the bonded MOs, HOs, and AOs:

$$E_T\left(atom-atom,msp^3\right)=\sum_{n=1}^{N}c_{s_n}E_T\left(atom-atom\left(s_n\right),msp^3\right) \tag{15.30}$$

where c_{s_n} is the multiple of the BO of s_n. The radius r_{msp^3} of the *atom* msp^3 shell of each bonding atom is given by the Coulombic energy using the initial energy $E_{Coulomb}\left(atom,msp^3\right)$ and $E_T\left(atom-atom,msp^3\right)$, the energy change of each *atom* msp^3 shell with the formation of each atom-atom-bond MO:

$$r_{msp^3}=\frac{-e^2}{8\pi\varepsilon_0 a_0\left(E_{Coulonb}\left(atom,msp^3\right)+E_T\left(atom-atom,msp^3\right)\right)} \tag{15.31}$$

where $E_{Coulomb}\left(C2sp^3\right)=-14.825751\,eV$. The Coulombic energy $E_{Coulomb}\left(mol.atom,msp^3\right)$ of the outer electron of the *atom* msp^3 shell is given by Eq. (15.19). In the case that during hybridization, at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E(magnetic)$ (Eq. (15.15)) at the initial radius r of the AO electron. Then, the energy $E\left(mol.atom,msp^3\right)$ of the outer electron

of the *atom* msp^3 shell is given by the sum of $E_{Coulomb}\left(mol.atom,msp^3\right)$ and $E(magnetic)$ (Eq. (15.20)). $E_T\left(atom-atom,msp^3\right)$, the energy change of each *atom* msp^3 shell with the formation of the atom-atom-bond MO is given by the difference between $E\left(mol.atom,msp^3\right)$ and $E\left(atom,msp^3\right)$ given by Eq. (15.21). Using Eq. (15.23) for $E_{Coulomb}\left(C,2sp^3\right)$ in Eq. (15.31), the single bond order energies given by Eqs. (15.18-15.27) and shown in Table 15.1, and the linear combination energies (Eqs. (15.28-15.30)), the parameters of linear combinations of bond orders and linear combinations of mixed bond orders are given in Table 15.2.

Table 15.2. The final values of r_{C2sp3}, $E_{Coulomb}(C2sp^3)$, and $E(C2sp^3)$ and the resulting $E_T(\overset{BO}{C-C},C2sp^3)$ of the MO comprising a linear combination of H_2-type ellipsoidal MOs and corresponding HOs of single or mixed bond order where c_{s_n} is the multiple of the bond order parameter $E_T(atom-atom\ (s_n), msp^3)$ given in Table 15.1.

MO Bond Order (BO)	s_1	c_{s_1}	s_2	c_{s_2}	s_3	c_{s_3}	$r_{C2sp^3}(a_0)$ Final	$E_{Coulomb}\left(C2sp^3\right)$ (eV) Final	$E\left(C2sp^3\right)$ (eV) Final	$E_T\left(\overset{BO}{C-C},C2sp^3\right)$ (eV)

Consider next the radius of the AO or HO due to the contribution of charge to more than one bond. The energy contribution due to the charge donation at each atom such as carbon superimposes linearly. In general, the radius r_{mol2sp^3} of the $C2sp^3$ HO of a carbon atom of a given molecule is calculated using Eq. (14.514) by considering $\sum E_{T_{mol}}\left(MO,2sp^3\right)$, the total energy donation to all bonds with which it participates in bonding. The general equation for the radius is given by:

$$r_{mol2sp^3}=\frac{-e^2}{8\pi\varepsilon_0\left(E_{Coulomb}\left(C,2sp^3\right)+\sum E_{T_{mol}}\left(MO,2sp^3\right)\right)}=\frac{e^2}{8\pi\varepsilon_0\left(e14.825751\ eV+\sum\left|E_{T_{mol}}\left(MO,2sp^3\right)\right|\right)} \tag{15.32}$$

The Coulombic energy $E_{Coulomb}\left(mol.atom,msp^3\right)$ of the outer electron of the *atom* msp^3 shell is given by Eq. (15.19). In the case that during hybridization, at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E(magnetic)$ (Eq. (15.15)) at the initial radius r of the AO electron. Then, the energy $E\left(mol.atom,msp^3\right)$ of the outer electron of the *atom* msp^3 shell is given by the sum of $E_{Coulomb}\left(mol.atom,msp^3\right)$ and $E(magnetic)$ (Eq. (15.20)).

For example, the $C2sp^3$ HO of each methyl group of an alkane contributes $-0.92918\ eV$ (Eq. (14.513)) to the corresponding single $C-C$ bond; thus, the corresponding $C2sp^3$ HO radius is given by Eq. (14.514). The $C2sp^3$ HO of each methylene group of C_nH_{2n+2} contributes $-0.92918\ eV$ to each of the two corresponding $C-C$ bond MOs. Thus, the radius (Eq. (15.32)), the Coulombic energy (Eq. (15.19)), and the energy (Eq. (15.20)) of each alkane methylene group are:

$$\begin{aligned}r_{alkaneC_{methylene}2sp^3}&=\frac{-e^2}{8\pi\varepsilon_0\left(E_{Coulomb}\left(C,2sp^3\right)+\sum E_{T_{alkane}}\left(methylene\ C-C,2sp^3\right)\right)}\\&=\frac{e^2}{8\pi\varepsilon_0\left(e14.825751\ eV+e0.92918\ eV+e0.92918\ eV\right)}=0.81549a_0\end{aligned} \tag{15.33}$$

$$E_{Coulomb}\left(C_{methylene}2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0\left(0.81549a_0\right)}=-16.68412\ eV \tag{15.34}$$

$$E\left(C_{methylene}2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0\left(0.81549a_0\right)}+\frac{2\pi\mu_0 e^2\hbar^2}{m_e^2\left(0.84317a_0\right)^3}=-16.49325\ \ eV \tag{15.35}$$

In the determination of the parameters of functional groups, heteroatoms bonding to $C2sp^3$ HOs to form MOs are energy matched to the $C2sp^3$ HOs. Thus, the radius and the energy parameters of a bonding heteroatom are given by the same equations as those for $C2sp^3$ HOs. Using Eqs. (15.15), (15.19-15.20), (15.24), and (15.32) in a generalized fashion, the final values of the radius of the HO or AO, $r_{Atom.HO.AO}$, $E_{Coulomb}\left(mol.atom,msp^3\right)$, and $E\left(C_{mol}2sp^3\right)$ are calculated using $\sum E_{T_{group}}\left(MO,2sp^3\right)$, the total energy donation to each bond with which an atom participates in bonding corresponding to the values of $E_T\left(C\overset{BO}{-}C,C2sp^3\right)$ of the MO due to charge donation from the AO or HO to the MO given in Tables 15.1 and 15.2.

Table 15.3.A. The final values of $r_{Atom.HO.AO}$, $E_{Coulomb}$ ($mol.atom$,msp^3), and $E(C_{mol}C2sp^3)$ calculated using the values of $E_T(C\overset{BO}{-}C,C2sp^3)$ given in Tables 15.1 and 15.2.

From Eq. (15.18), the general equation for the radius due to a total charge $-Qe$ of an AO or a HO that participates in bonding to form a MO is given by:

$$r_{msp^3}=\left(\sum_{q=Z-n}^{Z-1}(Z-q)-Q\right)\frac{-e^2}{8\pi\varepsilon_0 E_T\left(mol.atom,msp^3\right)} \tag{15.36}$$

By equating the radii of Eqs. (15.36) and (15.32), the total charge parameter Q of the AO or HO can be calculated wherein the excess charge is on the MO:

$$Q=\left(\sum_{q=Z-n}^{Z-1}(Z-q)\right)-\frac{\left|E_T\left(mol.atom,msp^3\right)\right|}{\left(e14.825751\ eV+\sum\left|E_{T_{mol}}\left(MO,2sp^3\right)\right|\right)} \tag{15.37}$$

The modulation of the constant function by the time and spherically harmonic functions as given in Eq. (1.29) time-averages to zero such that the charge density of any HO or AO is determined by the constant function. The charge density σ is then given by the fundamental charge $-e$ times the number of electrons n divided by the area of the spherical shell of radius r_{mol2sp^3} given by Eq. (15.32):

$$\sigma=\frac{(n-Q)(-e)}{\frac{4}{3}\pi r_{mol2sp^3}^2} \tag{15.38}$$

The charge density of an ellipsoidal MO in rectangular coordinates (Eqs. (11.42-11.45)) is:

$$\sigma = \frac{q}{4\pi abc}\frac{1}{\sqrt{\frac{x^2}{a^4}+\frac{y^2}{b^4}+\frac{z^2}{c^4}}} = \frac{q}{4\pi abc}D \tag{15.39}$$

where D is the distance from the origin to the tangent plane. The charge q is given by the fundamental electron charge $-e$ times the sum of parameter n_1 of Eqs. (15.51) and (15.61) and the charge donation parameter Q (Eq. (15.37)) of each AO or HO to the MO. Thus, the charge density of the MO is given by:

$$\sigma = \frac{-e\left(n_1+Q\right)}{4\pi abc}D \tag{15.40}$$

The charge density of the MO that is continuous with the surface of the AO or HO and any radial bisector current resulting from the intersection of two or more MOs as given in the Methane Molecule (CH_4) section is determined by the current continuity condition. Consider the continuity of the current due to the intersection of an MO with a corresponding AO or HO. The parameters of each point of intersection of each H_2-type ellipsoidal MO and the corresponding atom AO or HO determined from the polar equation of the ellipse are given by Eqs. (15.80-15.87). The overlap charge Δq is given by the total charge of the prolate-spheroidal MO minus the integral of the charge density of the MO over the area between curves of intersection with the AOs or HOs that forms the MO:

$$\Delta q = -e\left(n_1+Q\right) - \int \sigma dA = -e\left(n_1+Q\right)\left(1-\int \frac{D}{4\pi abc}dA\right) \tag{15.41}$$

The overlap charge of the prolate-spheroidal MO Δq is uniformly distributed on the external spherical surface of the AO or HO of radius $r^3_{mol2sp^3}$ such that the charge density σ from Eq. (15.41) is:

$$\sigma = \frac{\Delta q}{A} \tag{15.42}$$

where A is the external surface area of the AO or HO between the curves of intersection with the MO surface.

At the curves of intersection of two or more MOs where they occur, the current between the AO or HO shell and curves of mutual contact is projected onto and flows in the direction of the radial vector to the surface of the AO or HO shell. This current designated the bisector current (BC) meets the AO or HO surface and does not travel to distances shorter than its radius. Due to symmetry, a radial axis through the AO or HO exists such that current travels from the MOs to the AO or HO along the radial vector in one direction and returns to the MO along the radial vector in the opposite direction from the AO or HO surface to conserve current flow. The MO current onto the bisector currents and the connecting current on the external surface of the AO or HO must be continuously maintained. Given the corresponding constant MO ω (Eq. (11.24)), the continuity condition requires that the charge density on these surfaces times the area ($\propto r^{-2}$) must be a constant corresponding to constant current, and this current must be matched at the inflow from the MO to the inflow bisector current, the HO or AO external surface, the outflow bisector current, and the return current on the opposite surface of the MO. Thus, σ on each surface s having charge Δq_s is given by Eq. (15.42) wherein $\Delta q = \sum \Delta q_s$ and Δq is given by Eq. (15.41) with the integral over the MO area between curves of intersection of the MOs. A is surface area corresponding to each Δq_s of the bisector currents and the external surface of the AO or HO between the curves of intersection of the bisector current with the AO or HO surface. Since the potential of an MO is that of a point charge at infinity (Eq. (11.36)), an asymmetry in the distribution of charge between nonequivalent HOs or AOs of the MO occurs to maintain an energy match of the MO with the bridged orbitals. The charge must redistribute between the spherical orbitals to achieve a corresponding current-density that maintains constant current at the equivalent-energy condition according to the energy-matching factor such as c_2 or C_2 of Eqs. (15.51) and (15.61). Since the orbital energy and radius are reciprocally related, the contribution scales as the square of the ratio (over unity) of the energy of the resultant net positively-charged orbital and the initial matched energy of the resultant net negatively-charged orbital of the bond multiplied by the energy-matching factor (e.g. c_2 or C_2). The partial charges on the HOs or AOs corresponding to the charge contribution are equivalent to point charges centered on the nuclei. Due to symmetry, the bond moment μ of each functional group is along the internuclear axis and is calculated from the partial changes at the separation distance, the internuclear distance. The dipole moment of a given molecule is then given by the vector sum of the bond moments in the molecule. Thus, the dipole moment is given by taking into account the magnitude and direction of the bond moment of each functional group wherein the function-group bond moment stays constant from molecule to molecule and is in the vector direction of the internuclear axis as given in the Bonds and Dipole Moments section.

The angles at which any two prolate spheroidal $A-C$ and $B-C$-bond MOs intersect can be determined using Eq. (13.85) by equating the radii of the elliptic cross sections of the MOs:

$$\left(a_1-c_1'\right)\frac{1+\frac{c_1'}{a_1}}{1+\frac{c_1'}{a_1}\cos\theta_1'} = \left(a_2-c_2'\right)\frac{1+\frac{c_2'}{a_2}}{1+\frac{c_2'}{a_2}\cos\theta_2'} \tag{15.43}$$

and by using the following relationship between the polar angles θ_1' and θ_2':

$$\theta_{\angle ACB} = \theta_1' + \theta_2' - 360° \tag{15.44}$$

where $\theta_{\angle ACB}$ is the bond angle of atoms A and B with central atom C. From either angle, the polar radius of intersection can be determined using Eq. (13.85). An example for methane is shown in Eqs. (13.597-13.600). Using these coordinates and the radius of the AO or HO, the limits of the integrals for the determination of the charge densities as well as the regions of each charge density are determined.

The energy of the MO is matched to each of the participating outermost atomic or hybridized orbitals of the bonding atoms wherein the energy match includes the energy contribution due to the AO or HO's donation of charge to the MO. The force constant k' (Eq. (15.1)) is used to determine the ellipsoidal parameter c' (Eq. (15.2)) of each H_2-type-ellipsoidal-MO in terms of the central force of the foci. Then, c' is substituted into the energy equation (from Eq. (15.11)) which is set equal to n_1 times the total energy of H_2 where n_1 is the number of equivalent bonds of the MO and the energy of H_2, $-31.63536831\ eV$, Eq. (11.212) is the minimum energy possible for a prolate spheroidal MO. From the energy equation and the relationship between the axes, the dimensions of the MO are solved. The energy equation has the semimajor axis a as its only parameter. The solution of the semimajor axis a then allows for the solution of the other axes of each prolate spheroid and eccentricity of each MO (Eqs. (15.3-15.5)). The parameter solutions then allow for the component and total energies of the MO to be determined.

The total energy, $E_{T\,(H_2MO)}$, is given by the sum of the energy terms (Eqs. (15.6-15.11)) plus $E_T(AO/HO)$:

$$E_{T\,(H_2MO)} = V_e + T + V_m + V_p + E_T(AO/HO) \tag{15.45}$$

$$\begin{aligned} E_{T\,(H_2MO)} &= -\frac{n_1 e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\left[c_1c_2\left(2-\frac{a_0}{a}\right)\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}-1\right]+E_T(AO/HO) \\ &= -\frac{n_1 e^2}{8\pi\varepsilon_0 c'}\left[c_1c_2\left(2-\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]+E_T(AO/HO) \end{aligned} \tag{15.46}$$

where n_1 is the number of equivalent bonds of the MO, c_1 is the fraction of the H_2-type ellipsoidal MO basis function of a chemical bond of the group, c_2 is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of each chemical bond, and $E_T(AO/HO)$ is the total energy comprising the difference of the energy $E(AO/HO)$ of at least one atomic or hybrid orbital to which the MO is energy matched and any energy component $\Delta E_{H_2MO}(AO/HO)$ due to the AO or HO's charge donation to the MO.

$$E_T(AO/HO) = E(AO/HO) - \Delta E_{H_2MO}(AO/HO) \tag{15.47}$$

As specific examples given in previous sections, $E_T(AO/HO)$ is one from the group of:

$E_T(AO/HO) = E(O2p\ shell) = -E(ionization;\ O) = -13.6181\ eV$;

$E_T(AO/HO) = E(N2p\ shell) = -E(ionization;\ N) = -14.53414\ eV$;

$E_T(AO/HO) = E(C, 2sp^3) = -14.63489\ eV$;

$E_T(AO/HO) = E_{Coulomb}(Cl, 3sp^3) = -14.60295\ eV$;

$E_T(AO/HO) = E(ionization;\ C) + E(ionization;\ C^+)$;

$E_T(AO/HO) = E(C_{ethane}, 2sp^3) = -15.35946\ eV$;

$E_T(AO/HO) = E(C_{ethylene}, 2sp^3) - E(C_{ethylene}, 2sp^3)$;

$E_T(AO/HO) = E(C, 2sp^3) - 2E_T(C=C, 2sp^3) = -14.63489\ eV - (-2.26758\ eV)$;

$E_T(AO/HO) = E(C_{acetylene}, 2sp^3) - E(C_{acetylene}, 2sp^3) - E(C_{acetylene}, 2sp^3) = 16.20002\ eV$;

$E_T(AO/HO) = E(C, 2sp^3) - 2E_T(C\equiv C, 2sp^3) = -14.63489\ eV - (-3.13026\ eV)$;

$E_T(AO/HO) = E(C_{benzene}, 2sp^3) - E(C_{benzene}, 2sp^3)$;

$E_T(AO/HO) = E(C, 2sp^3) - E_T(C=C, 2sp^3) = -14.63489\ eV - (-1.13379\ eV)$, and

$E_T(AO/HO) = E(C_{alkane}, 2sp^3) = -15.56407\ eV$.

To solve the bond parameters and energies, $c' = a\sqrt{\frac{\hbar^2 4\pi\varepsilon_0}{m_e e^2 2C_1C_2 a}} = \sqrt{\frac{aa_0}{2C_1C_2}}$ (Eq. (15.2)) is substituted into $E_{T\,(H_2MO)}$ to:

give

$$E_{T\,(H_2MO)} = -\frac{n_1 e^2}{8\pi\varepsilon_0\sqrt{a^2-b^2}}\left[c_1c_2\left(2-\frac{a_0}{a}\right)\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}-1\right]+E_T\left(AO/HO\right)$$
$$= -\frac{n_1 e^2}{8\pi\varepsilon_0 c'}\left[c_1c_2\left(2-\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'}-1\right]+E_T\left(AO/HO\right) \quad (15.48)$$
$$= -\frac{n_1 e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2C_1C_2}}}\left[c_1c_2\left(2-\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{2C_1C_2}}}{a-\sqrt{\frac{aa_0}{2C_1C_2}}}-1\right]+E_T\left(AO/HO\right)$$

The total energy is set equal to $E(basis\ energies)$ which in the most general case is given by the sum of a first integer n_1 times the total energy of H_2 minus a second integer n_2 times the total energy of H, minus a third integer n_3 times the valence energy of $E(AO)$ (e.g. $E(N) = -14.53414\ eV$) where the first integer can be $1,2,3...$, and each of the second and third integers can be $0,1,2,3....$

$$E(basis\ energies) = n_1\left(-31.63536831\ eV\right) - n_2\left(-13.605804\ eV\right) - n_3E\left(AO\right) \quad (15.49)$$

In the case that the MO bonds two atoms other than hydrogen, $E(basis\ energies)$ is n_1 times the total energy of H_2 where n_1 is the number of equivalent bonds of the MO and the energy of H_2, $-31.63536831\ eV$, Eq. (11.212) is the minimum energy possible for a prolate spheroidal MO:

$$E(basis\ energies) = n_1\left(-31.63536831\ eV\right) \quad (15.50)$$

$E_{T\,(H_2MO)}$, is set equal to $E(basis\ energies)$, and the semimajor axis a is solved. Thus, the semimajor axis a is solved from the equation of the form:

$$-\frac{n_1 e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2C_1C_2}}}\left[c_1c_2\left(2-\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{2C_1C_2}}}{a-\sqrt{\frac{aa_0}{2C_1C_2}}}-1\right]+E_T\left(AO/HO\right) = E(basis\ energies) \quad (15.51)$$

The distance from the origin of the H_2-type-ellipsoidal-MO to each focus c', the internuclear distance $2c'$, and the length of the semiminor axis of the prolate spheroidal H_2-type MO $b = c$ are solved from the semimajor axis a using Eqs. (15.2-15.4). Then, the component energies are given by Eqs. (15.6-15.9) and (15.48).

The total energy of the MO of the functional group, $E_{T\,(MO)}$, is the sum of the total energy of the components comprising the energy contribution of the MO formed between the participating atoms and $E_T\left(atom-atom, msp^3.AO\right)$, the change in the energy of the AOs or HOs upon forming the bond. From Eqs. (15.48-15.49), $E_{T\,(MO)}$ is:

$$E_{T\,(MO)} = E(basis\ energies) + E_T\left(atom-atom, msp^3.AO\right) \quad (15.52)$$

During bond formation, the electrons undergo a reentrant oscillatory orbit with vibration of the nuclei, and the corresponding energy $\overline{E}_{osc}$ is the sum of the Doppler, $\overline{E}_D$, and average vibrational kinetic energies, $\overline{E}_{Kvib}$:

$$\overline{E}_{osc} = n_1\left(\overline{E}_D + \overline{E}_{Kvib}\right) = n_1\left(E_{h\nu}\sqrt{\frac{2\overline{E}_K}{m_e c^2}} + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \quad (15.53)$$

where n_1 is the number of equivalent bonds of the MO, k is the spring constant of the equivalent harmonic oscillator, and μ is the reduced mass. The angular frequency of the reentrant oscillation in the transition state corresponding to $\overline{E}_D$ is determined by the force between the central field and the electrons in the transition state. The force and its derivative are given by:

$$f\left(R\right) = -c_{BO}\frac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0 R^3} \quad (15.54)$$

and

$$f'\left(a\right) = 2c_{BO}\frac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0 R^3} \quad (15.55)$$

such that the angular frequency of the oscillation in the transition state is given by:

$$\omega = \sqrt{\frac{\left[\frac{-3}{a}f\left(a\right) - f'\left(a\right)\right]}{m_e}} = \sqrt{\frac{k}{m_e}} = \sqrt{\frac{c_{BO}\frac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0 R^3}}{m_e}} \quad (15.56)$$

where R is the semimajor axis a or the semiminor axis b depending on the eccentricity of the bond that is most representative of the oscillation in the transition state, c_{BO} is the bond-order factor which is 1 for a single bond and when the MO comprises n_1 equivalent single bonds as in the case of functional groups. c_{BO} is 4 for an independent double bond as in the case of the CO_2 and NO_2 molecules and 9 for an independent triple bond. C_{1o} is the fraction of the H_2-type ellipsoidal MO basis function of the oscillatory transition state of a chemical bond of the group, and C_{2o} is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of the transition state of the chemical bond. Typically, $C_{1o} = C_1$ and $C_{2o} = C_2$. The kinetic energy, E_K, corresponding to $\bar{E}_D$ is given by Planck's equation for functional groups:

$$\bar{E}_K = \hbar\omega = \hbar\sqrt{\frac{\frac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0 R^3}}{m_e}} \tag{15.57}$$

The Doppler energy of the electrons of the reentrant orbit is:

$$\bar{E}_D \cong E_{h\nu}\sqrt{\frac{2\bar{E}_K}{m_e c^2}} = E_{h\nu}\sqrt{\frac{2\hbar\sqrt{\frac{\frac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0 R^3}}{m_e}}}{m_e c^2}} \tag{15.58}$$

$\bar{E}_{osc}$ given by the sum of $\bar{E}_D$ and $\bar{E}_{Kvib}$ is:

$$\bar{E}_{osc\,(group)} = n_1\left(\bar{E}_D + \bar{E}_{Kvib}\right) = n_1\left(E_{h\nu}\sqrt{\frac{2\hbar\sqrt{\frac{\frac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0 R^3}}{m_e}}}{m_e c^2}} + E_{vib}\right) \tag{15.59}$$

$E_{h\nu}$ of a group having n_1 bonds is given by $E_{T\,(MO)}/n_1$ such that:

$$\bar{E}_{osc} = n_1\left(\bar{E}_D + \bar{E}_{Kvib}\right) = n_1\left(E_{T\,(MO)}/n_1\sqrt{\frac{2\bar{E}_K}{Mc^2}} + \frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \tag{15.60}$$

$E_{T+osc\,(Group)}$ is given by the sum of $E_{T\,(MO)}$ (Eq. (15.51)) and $\bar{E}_{osc}$ (Eq. (15.60)).

$$\begin{aligned} E_{T+osc\,(Group)} = E_{T\,(MO)} + \bar{E}_{osc} &= \left(\begin{array}{l} \left(-\frac{n_1 e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2C_1C_2}}}\left[c_1c_2\left(2-\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{2C_1C_2}}}{a-\sqrt{\frac{aa_0}{2C_1C_2}}}-1\right]\right) \\ +E_T\left(AO/HO\right)+E_T\left(atom-atom, msp^3.AO\right) \end{array}\right) \\ &\left(\left[1+\sqrt{\frac{2\hbar\sqrt{\frac{\frac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0 R^3}}{m_e}}}{m_e c^2}}\right]+n_1\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \\ &= \left(E(basis\ energies)+E_T\left(atom-atom, msp^3.AO\right)\right)\left[1+\sqrt{\frac{2\hbar\sqrt{\frac{\frac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0 R^3}}{m_e}}}{m_e c^2}}\right]+n_1\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}} \end{aligned} \tag{15.61}$$

The total energy of the functional group $E_{T\,(group)}$ is the sum of the total energy of the components comprising the energy contribution of the MO formed between the participating atoms, $E(basis\ energies)$, the change in the energy of the AOs or HOs upon forming the bond ($E_T\left(atom-atom, msp^3.AO\right)$), the energy of oscillation in the transition state, and the change in magnetic energy with bond formation, E_{mag}. From Eq. (15.61), the total energy of the group $E_{T\,(Group)}$ is:

$$E_T\left(_{Group}\right)=\left(\begin{array}{l}\left(E(basis\ energies)+E_T\left(atom-atom,msp^3.AO\right)\right)\left[1+\sqrt{\dfrac{2\hbar\sqrt{\dfrac{\dfrac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0R^3}}{m_e}}}{m_ec^2}}\right]\\ +n_1\overline{E}_{Kvib}+E_{mag}\end{array}\right) \tag{15.62}$$

The change in magnetic energy E_{mag} which arises due to the formation of unpaired electrons in the corresponding fragments relative to the bonded group is given by:

$$E_{mag}=c_3\frac{2\pi\mu_0e^2\hbar^2}{m_e^2r^3}=c_3\frac{8\pi\mu_0\mu_B^2}{r^3} \tag{15.63}$$

where *r* is the radius of the atom that reacts to form the bond and c_3 is the number of electron pairs.

$$E_T\left(_{Group}\right)=\left(\begin{array}{l}\left(E(basis\ energies)+E_T\left(atom-atom,msp^3.AO\right)\right)\left[1+\sqrt{\dfrac{2\hbar\sqrt{\dfrac{\dfrac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0R^3}}{m_e}}}{m_ec^2}}\right]\\ +n_1\overline{E}_{Kvib}+c_3\dfrac{8\pi\mu_0\mu_B^2}{r^3}\end{array}\right) \tag{15.64}$$

The total bond energy of the group $E_D\left(_{Group}\right)$ is the negative difference of the total energy of the group (Eq. (15.64)) and the total energy of the two starting orbitals given by the sum of $c_4E_{initial}\left(c_4\ AO/HO\right)$ and $c_5E_{initial}\left(c_5\ AO/HO\right)$:

$$E_D\left(_{Group}\right)=-\left(\begin{array}{l}\left(E(basis\ energies)+E_T\left(atom-atom,msp^3.AO\right)\right)\left[1+\sqrt{\dfrac{2\hbar\sqrt{\dfrac{\dfrac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0R^3}}{m_e}}}{m_ec^2}}\right]\\ +n_1\overline{E}_{Kvib}+c_3\dfrac{8\pi\mu_0\mu_B^2}{r^3}-\left(c_4E_{initial}\left(c_4AO/HO\right)+c_5E_{initial}\left(c_5\ AO/HO\right)\right)\end{array}\right) \tag{15.65}$$

In the case of organic molecules, the atoms of the functional groups are energy matched to the $C2sp^3$ HO such that:

$$E\left(AO/HO\right)=-14.63489\ eV \tag{15.66}$$

For examples of E_{mag} from previous sections:

$$E_{mag}\left(C2sp^3\right)=c_3\frac{8\pi\mu_0\mu_B^2}{r^3}=c_3\frac{8\pi\mu_0\mu_B^2}{\left(0.91771a_0\right)^3}=c_30.14803\ eV \tag{15.67}$$

$$E_{mag}\left(O2p\right)=c_3\frac{8\pi\mu_0\mu_B^2}{r^3}=c_3\frac{8\pi\mu_0\mu_B^2}{a_0^3}=c_30.11441\ eV \tag{15.68}$$

$$E_{mag}\left(N2p\right)=c_3\frac{8\pi\mu_0\mu_B^2}{r^3}=c_3\frac{8\pi\mu_0\mu_B^2}{\left(0.93084a_0\right)^3}=c_30.14185\ eV \tag{15.69}$$

In the general case of the solution of an organic functional group, the geometric bond parameters are solved from the semimajor axis and the relationships between the parameters by first using Eq. (15.51) to arrive at a. Then, the remaining parameters are determined using Eqs. (15.1-15.5). Next, the energies are given by Eqs. (15.61-15.68). To meet the equipotential condition for the union of the H_2-type-ellipsoidal-MO and the HO or AO of the atom of a functional group, the factor c_2 of a H_2-type ellipsoidal MO in principal Eqs. (15.51) and (15.61) may given by:

(i) one:

$$c_2=1 \tag{15.70}$$

(ii) the ratio that is less than one of 13.605804 eV, the magnitude of the Coulombic energy between the electron and proton of H given by Eq. (1.264), and the magnitude of the Coulombic energy of the participating AO or HO of the atom, $E_{Coulomb}\left(MO.atom,msp^3\right)$ given by Eqs. (15.19) and (15.31-15.32). For $\left|E_{Coulomb}\left(MO.atom,msp^3\right)\right|$>13.605804 eV:

$$c_2 = \frac{\frac{e^2}{8\pi\varepsilon_0 a_0}}{\frac{e^2}{8\pi\varepsilon_0 r_{A-B\ AorBsp^3}}} = \frac{13.605804\ eV}{\left|E_{Coulomb}\left(MO.atom, msp^3\right)\right|} \tag{15.71}$$

For $\left|E_{Coulomb}\left(MO.atom, msp^3\right)\right| < 13.605804\ eV$:

$$c_2 = \frac{\frac{e^2}{8\pi\varepsilon_0 r_{A-B\ AorBsp^3}}}{\frac{e^2}{8\pi\varepsilon_0 a_0}} = \frac{\left|E_{Coulomb}\left(MO.atom, msp^3\right)\right|}{13.605804\ eV} \tag{15.72}$$

(iii) the ratio that is less than one of 13.605804 eV, the magnitude of the Coulombic energy between the electron and proton of H given by Eq. (1.264), and the magnitude of the valence energy, $E(valence)$, of the participating AO or HO of the atom where $E(valence)$ is the ionization energy or $E\left(MO.atom, msp^3\right)$ given by Eqs. (15.20) and (15.31-15.32). For $\left|E(valence)\right| > 13.605804\ eV$:

$$c_2 = \frac{\frac{e^2}{8\pi\varepsilon_0 a_0}}{\frac{e^2}{8\pi\varepsilon_0 r_{A-B\ AorBsp^3}}} = \frac{13.605804\ eV}{\left|E(valence)\right|} \tag{15.73}$$

For $\left|E(valence)\right| < 13.605804\ eV$:

$$c_2 = \frac{\frac{e^2}{8\pi\varepsilon_0 r_{A-B\ AorBsp^3}}}{\frac{e^2}{8\pi\varepsilon_0 a_0}} = \frac{\left|E(valence)\right|}{13.605804\ eV} \tag{15.74}$$

(iv) the ratio that is less than one of the magnitude of the Coulombic energy of the participating AO or HO of a first atom, $E_{Coulomb}\left(MO.atom, msp^3\right)$ given by Eqs. (15.19) and (15.31-15.32), and the magnitude of the valence energy, $E(valence)$, of the participating AO or HO of a second atom to which the first is energy matched where $E(valence)$ is the ionization energy or $E\left(MO.atom, msp^3\right)$ given by Eqs. (15.20) and (15.31-15.32). For $\left|E_{Coulomb}\left(MO.atom, msp^3\right)\right| > E(valence)$:

$$c_2 = \frac{\left|E(valence)\right|}{\left|E_{Coulomb}\left(MO.atom, msp^3\right)\right|} \tag{15.75}$$

For $\left|E_{Coulomb}\left(MO.atom, msp^3\right)\right| < E(valence)$:

$$c_2 = \frac{\left|E_{Coulomb}\left(MO.atom, msp^3\right)\right|}{\left|E(valence)\right|} \tag{15.76}$$

(v) the ratio of the magnitude of the valence-level energies, $E_n(valence)$, of the AO or HO of the nth participating atom of two that are energy matched where $E(valence)$ is the ionization energy or $E\left(MO.atom, msp^3\right)$ given by Eqs. (15.20) and (15.31-15.32):

$$c_2 = \frac{E_1(valence)}{E_2(valence)} \tag{15.77}$$

(vi) the factor that is the ratio of the hybridization factor $c_2(1)$ of the valence AO or HO of a first atom and the hybridization factor $c_2(2)$ of the valence AO or HO of a second atom to which the first is energy matched where $c_2(n)$ is given by Eqs. (15.71-15.77); alternatively c_2 is the hybridization factor $c_2(1)$ of the valence AOs or HOs a first pair of atoms and the hybridization factor $c_2(2)$ of the valence AO or HO a third atom or second pair to which the first two are energy matched:

$$c_2 = \frac{c_2(1)}{c_2(2)} \tag{15.78}$$

(vii) the factor that is the product of the hybridization factor $c_2(1)$ of the valence AO or HO of a first atom and the hybridization factor $c_2(2)$ of the valence AO or HO of a second atom to which the first is energy matched where $c_2(n)$ is given by Eqs. (15.71-15.78); alternatively c_2 is the hybridization factor $c_2(1)$ of the valence AOs or HOs a first pair of atoms and the hybridization factor $c_2(2)$ of the valence AO or HO a third atom or second pair to which the first two are energy matched:

$$c_2 = c_2(1)c_2(2) \tag{15.79}$$

The hybridization factor c_2 corresponds to the force constant k (Eqs. (11.65) and (13.58)). In the case that the valence or Coulombic energy of the AO or HO is less than $13.605804\ eV$, the magnitude of the Coulombic energy between the electron and proton of H given by Eq. (1.264), then C_2 corresponding to k' (Eq. (15.1)) is given by Eqs. (15.71-15.79).

Specific examples of the factors c_2 and C_2 of a H_2-type ellipsoidal MO of Eq. (15.60) given in following sections are:

$$c_2\left(C2sp^3HO\ to\ F\right) = \frac{E\left(C,2sp^3\right)}{E(F)}c_2\left(C2sp^3HO\right) = \frac{-14.63489\ eV}{-17.42282\ eV}(0.91771) = 0.77087;$$

$$C_2\left(C2sp^3HO\ to\ Cl\right) = \frac{E(Cl)}{E\left(C,2sp^3\right)}c_2\left(C2sp^3HO\right) = \frac{-12.96764\ eV}{-14.63489\ eV}(0.91771) = 0.81317;$$

$$C_2\left(C2sp^3HO\ to\ Br\right) = \frac{E(Br)}{E\left(C,2sp^3\right)}c_2\left(C2sp^3HO\right) = \frac{-11.81381\ eV}{-14.63489\ eV}(0.91771) = 0.74081;$$

$$C_2\left(C2sp^3HO\ to\ I\right) = \frac{E(I)}{E\left(C,2sp^3\right)}c_2\left(C2sp^3HO\right) = \frac{-10.45126\ eV}{-14.63489\ eV}(0.91771) = 0.65537;$$

$$c_2\left(C2sp^3HO\ to\ O\right) = \frac{E(O)}{E\left(C,2sp^3\right)}c_2\left(C2sp^3HO\right) = \frac{-13.61806\ eV}{-14.63489\ eV}(0.91771) = 0.85395;$$

$$c_2\left(H\ to\ 1°N\right) = \frac{E(N)}{E\left(C,2sp^3\right)} = \frac{-14.53414\ eV}{-15.35946\ eV} = 0.94627;$$

$$c_2\left(C2sp^3HO\ to\ N\right) = \frac{E(N)}{E\left(C,2sp^3\right)}c_2\left(C2sp^3HO\right) = \frac{-14.53414\ eV}{-14.63489\ eV}(0.91771) = 0.91140;$$

$$c_2\left(H\ to\ 2°N\right) = \frac{E(N)}{E\left(C,2sp^3\right)} = \frac{-14.53414\ eV}{-15.56407\ eV} = 0.93383;$$

$$C_2\left(S3p\ to\ H\right) = \frac{E(S,3p)}{E(H)} = \frac{-10.36001\ eV}{-13.60580\ eV} = 0.76144;$$

$$c_2\left(H\ to\ aniline\ N\right)=\frac{E\left(N\right)}{E\left(C,2sp^3\right)}=\frac{-14.53414\ eV}{-15.76868\ eV}=0.92171;$$

$$c_2\left(arylC2sp^3HO\ to\ N\right)=\frac{E\left(N\right)}{E\left(C,2sp^3\right)}c_2\left(arylC2sp^3HO\right)=\frac{-14.53414\ eV}{-14.63489\ eV}\left(0.85252\right)=0.84665\text{, and}$$

$$C_2\left(S3p\ to\ aryl\text{-}type\ C2sp^3HO\right)=\frac{E\left(S,3p\right)}{E\left(C,2sp^3\right)}=\frac{-10.36001\ eV}{-15.76868\ eV}=0.65700\,.$$

MO INTERCEPT ANGLES AND DISTANCES

Consider the general case of Eqs. (13.84-13.95), wherein the nucleus of a B atom and the nucleus of a A atom comprise the foci of each H_2-type ellipsoidal MO of an $A-B$ bond. The parameters of the point of intersection of each H_2-type ellipsoidal MO and the A-atom AO are determined from the polar equation of the ellipse:

$$r=r_0\frac{1+e}{1+e\cos\theta'} \tag{15.80}$$

The radius of the A shell is r_A, and the polar radial coordinate of the ellipse and the radius of the A shell are equal at the point of intersection such that:

$$r_A=\left(a-c'\right)\frac{1+\frac{c'}{a}}{1+\frac{c'}{a}\cos\theta'} \tag{15.81}$$

The polar angle θ' at the intersection point is given by:

$$\theta'=\cos^{-1}\left(\frac{a}{c'}\left(\left(a-c'\right)\frac{1+\frac{c'}{a}}{r_A}-1\right)\right) \tag{15.82}$$

Then, the angle $\theta_{A\,AO}$ the radial vector of the A AO makes with the internuclear axis is:

$$\theta_{A\,AO}=180°-\theta' \tag{15.83}$$

The Cartesian $\mathbf{i}$-coordinate of the interception point of the MO and the AO can be calculated using the MO ellipsoidal parameters by first calculating the parametric angle in Eq. (11.83) that matches Cartesian $\mathbf{j}$-coordinate components at the point of intersection. Thus, the matching elliptic parametric angle $\omega t=\theta_{H_2MO}$ satisfies the following relationship:

$$r_A\sin\theta_{A\,AO}=b\sin\theta_{H_2MO} \tag{15.84}$$

such that

$$\theta_{H_2MO}=\sin^{-1}\frac{r_a\sin\theta_{A\,AO}}{b} \tag{15.85}$$

The distance d_{H_2MO} along the internuclear axis from the origin of H_2-type ellipsoidal MO to the point of intersection of the orbitals is given by:

$$d_{H_2MO}=a\cos\theta_{H_2MO} \tag{15.86}$$

The distance $d_{A\,AO}$ along the internuclear axis from the origin of the A atom to the point of intersection of the orbitals is given by:

$$d_{A\,AO}=c'-d_{H_2MO} \tag{15.87}$$

BOND ANGLES

Further consider an ACB MO comprising a linear combination of $C-A$-bond and $C-B$-bond MOs where C is the general central atom. A bond is also possible between the A and B atoms of the $C-A$ and $C-B$ bonds. Such $A-B$ bonding would decrease the $C-A$ and $C-B$ bond strengths since electron density would be shifted from the latter bonds to the former bond. Thus, the $\angle ACB$ bond angle is determined by the condition that the total energy of the H_2-type ellipsoidal MO between the

terminal A and B atoms is zero. The force constant k' of a H_2-type ellipsoidal MO due to the equivalent of two point charges at the foci is given by:

$$k' = \frac{C_1 C_2 2e^2}{4\pi\varepsilon_0} \tag{15.88}$$

where C_1 is the fraction of the H_2-type ellipsoidal MO basis function of a chemical bond of the molecule which is 0.75 (Eq. (13.59)) for a terminal $A-H$ (A is H or other atom) and 1 otherwise and C_2 is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of the chemical bond and is equal to the corresponding factor of Eqs. (15.51) and (15.61). The distance from the origin of the MO to each focus c' of the $A-B$ ellipsoidal MO is given by:

$$c' = a\sqrt{\frac{\hbar^2 4\pi\varepsilon_0}{m_e e^2 2C_1 C_2 a}} = \sqrt{\frac{aa_0}{2C_1 C_2}} \tag{15.89}$$

The internuclear distance is:

$$2c' = 2\sqrt{\frac{aa_0}{2C_1 C_2}} \tag{15.90}$$

The length of the semiminor axis of the prolate spheroidal $A-B$ MO $b=c$ is given by Eq. (15.4).

The component energies and the total energy, $E_T(_{H_2MO})$, of the $A-B$ bond are given by the energy equations (Eqs. (11.207-11.212), (11.213-11.217), and (11.239)) of H_2 except that the terms based on charge are multiplied by c_{BO}, the bond-order factor which is 1 for a single bond and when the MO comprises n_1 equivalent single bonds as in the case of functional groups. c_{BO} is 4 for an independent double bond as in the case of the CO_2 and NO_2 molecules. The kinetic energy term is multiplied by c'_{BO} which is 1 for a single bond, 2 for a double bond, and 9/2 for a triple bond. The electron energy terms are multiplied by c_1, the fraction of the H_2-type ellipsoidal MO basis function of a terminal chemical bond, which is 0.75 (Eq. (13.233)) for a terminal $A-H$ (A is H or other atom) and 1 otherwise. The electron energy terms are further multiplied by c_2', the hybridization or energy-matching factor that results in an equipotential energy match of the participating at least two atomic orbitals of each terminal bond. Furthermore, when $A-B$ comprises atoms other than H, $E_T\left(atom-atom, msp^3.AO\right)$, the energy component due to the AO or HO's charge donation to the terminal MO, is added to the other energy terms to give $E_T(_{H_2MO})$:

$$E_T(_{H_2MO}) = \frac{-e^2}{8\pi\varepsilon_0 c'}\left[c_1 c_2'\left(2c_{BO} - c'_{BO}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'} - 1\right] + E_T\left(atom-atom, msp^3.AO\right) \tag{15.91}$$

The radiation reaction force in the case of the vibration of $A-B$ in the transition state corresponds to the Doppler energy, E_D, given by Eq. (11.181) that is dependent on the motion of the electrons and the nuclei. The total energy that includes the radiation reaction of the $A-B$ MO is given by the sum of $E_T(_{H_2MO})$ (Eq. (15.91)) and $\overline{E}_{osc}$ given by Eqs. (11.213-11.220), (11.231-11.236), and (11.239-11.240). Thus, the total energy $E_T\left(A-B\right)$ of the $A-B$ MO including the Doppler term is:

$$E_T\left(A-B\right) = \left[\left(\frac{-e^2}{8\pi\varepsilon_0 c'}\left[c_1 c_2'\left(2c_{BO} - c'_{BO}\frac{a_0}{a}\right)\ln\frac{a+c'}{a-c'} - 1\right] + E_T\left(atom-atom, msp^3.AO\right)\right)\right.$$
$$\left.\left[1 + \sqrt{\frac{2\hbar\sqrt{\frac{c_{BO}\frac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0 a^3}}{m_e}}}{m_e c^2}}\right] + \frac{1}{2}\hbar\sqrt{\frac{c_{BO}\frac{c_1 c_2' e^2}{8\pi\varepsilon_0 a^3} - \frac{c_{BO}e^2}{8\pi\varepsilon_0\left(a+c'\right)^3}}{\mu}}\right] \tag{15.92}$$

where C_{1o} is the fraction of the H_2-type ellipsoidal MO basis function of the oscillatory transition state of the $A-B$ bond which is 0.75 (Eq. (13.233)) in the case of H bonding to a central atom and 1 otherwise, C_{2o} is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of the transition state of the chemical bond, and $\mu = \frac{m_1 m_2}{m_1 + m_2}$ is the reduced mass of the nuclei given by Eq. (11.154). To match the boundary condition that the total energy of the $A-B$ ellipsoidal MO is zero, $E_T\left(A-B\right)$ given by Eq. (15.92) is set equal to zero. Substitution of Eq. (15.90) into Eq. (15.92) gives:

$$0=\left[\left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2C_1C_2}}}\left[c_1c_2'\left(2c_{BO}-c'_{BO}\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{2C_1C_2}}}{a-\sqrt{\frac{aa_0}{2C_1C_2}}}-1\right]+E_T\left(atom-atom,msp^3.AO\right)\right)\left[1+\sqrt{\frac{2\hbar\sqrt{\frac{c_{BO}\frac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0a^3}}{m_e}}}{m_ec^2}}\right]+\frac{1}{2}\hbar\sqrt{\frac{c_{BO}\frac{c_1c_2'e^2}{8\pi\varepsilon_0a^3}-\frac{c_{BO}e^2}{8\pi\varepsilon_0\left(a+\sqrt{\frac{aa_0}{2C_1C_2}}\right)^3}}{\mu}}\right] \tag{15.93}$$

The vibrational energy-term of Eq. (15.93) is determined by the forces between the central field and the electrons and those between the nuclei (Eqs. (11.141-11.145)). The electron-central-field force and its derivative are given by:

$$f\left(a\right)=-c_{BO}\frac{c_1c_2'e^2}{4\pi\varepsilon_0a^3} \tag{15.94}$$

and

$$f'\left(a\right)=2c_{BO}\frac{c_1c_2'e^2}{4\pi\varepsilon_0a^3} \tag{15.95}$$

The nuclear repulsion force and its derivative are given by:

$$f\left(a+c'\right)=\frac{e^2}{8\pi\varepsilon_0\left(a+c'\right)^2} \tag{15.96}$$

and

$$f'\left(a+c'\right)=-\frac{e^2}{4\pi\varepsilon_0\left(a+c'\right)^3} \tag{15.97}$$

such that the angular frequency of the oscillation is given by:

$$\omega=\sqrt{\frac{\left[\frac{-3}{a}f\left(a\right)-f'\left(a\right)\right]}{\mu}}=\sqrt{\frac{k}{m_e}}=\sqrt{\frac{c_{BO}\frac{c_1c_2'e^2}{4\pi\varepsilon_0a^3}-\frac{e^2}{8\pi\varepsilon_0\left(a+c'\right)^2}}{\mu}} \tag{15.98}$$

Since both terms of $\overline{E}_{osc}=\overline{E}_D+\overline{E}_{Kvib}$ are small due to the large values of a and c', to very good approximation, a convenient form of Eq. (15.93) which is evaluated to determine the bond angles of functional groups is given by:

$$0=\left[\left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2C_1C_2}}}\left[c_1c_2'\left(2-\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{2C_1C_2}}}{a-\sqrt{\frac{aa_0}{2C_1C_2}}}-1\right]+E_T\left(atom-atom,msp^3.AO\right)\right)\left[1+\sqrt{\frac{2\hbar\sqrt{\frac{c_1e^2}{4\pi\varepsilon_0a^3}}}{m_ec^2}}\right]+\frac{1}{2}\hbar\sqrt{\frac{\frac{c_1e^2}{8\pi\varepsilon_0a^3}-\frac{e^2}{8\pi\varepsilon_0\left(a+\sqrt{\frac{aa_0}{2C_1C_2}}\right)^3}}{\mu}}\right] \tag{15.99}$$

From the energy relationship given by Eq. (15.99) and the relationship between the axes given by Eqs. (15.2-15.5), the dimensions of the $A-B$ MO can be solved. The most convenient way to solve Eq. (15.99) is by the reiterative technique using a computer.

A factor c_2 of a given atom in the determination of c_2' for calculating the zero of the total $A-B$ bond energy is typically given by Eqs. (15.71-15.74). In the case of a $H-H$ terminal bond of an alkyl or alkenyl group, c_2' is typically the ratio of c_2 of Eq. (15.71) for the $H-H$ bond which is one and c_2 of the carbon of the corresponding $C-H$ bond:

$$c_2'=\frac{1}{c_2(C2sp^3)}=\frac{E_{Coulomb}\left(C-H\ C2sp^3\right)}{13.605804\ eV} \tag{15.100}$$

In the case of the determination of the bond angle of the ACH MO comprising a linear combination of $C-A$-bond and $C-H$-bond MOs where A and C are general, C is the central atom, and c_2 for an atom is given by Eqs. (15.71-15.79), c_2' of the

$A-H$ terminal bond is typically the ratio of c_2 of the A atom for the $A-H$ terminal bond and c_2 of the C atom of the corresponding $C-H$ bond:

$$c_2' = \frac{c_2(A(A-H)msp^3)}{c_2(C(C-H)msp^3)} \tag{15.101}$$

In the case of the determination of the bond angle of the COH MO of an alcohol comprising a linear combination of $C-O$-bond and $O-H$ -bond MOs where C, O, and H are carbon, oxygen, and hydrogen, respectively, c_2' of the $C-H$ terminal bond is typically 0.91771 since the oxygen and hydrogen atoms are at the Coulomb potential of a proton and an electron (Eqs. (1.257) and (10.162), respectively) that is energy matched to the $C2sp^3$ HO.

In the determination of the hybridization factor c_2' of Eq. (15.99) from Eqs. (15.71-15.79), the Coulombic energy, $E_{Coulomb}\left(MO.atom, msp^3\right)$, or the energy, $E\left(MO.atom, msp^3\right)$, the radius $r_{A-B\ AorBsp^3}$ of the A or B AO or HO of the heteroatom of the $A-B$ terminal bond MO such as the $C2sp^3$ HO of a terminal $C-C$ bond is calculated using Eq. (15.32) by considering $\sum E_{T_{mol}}\left(MO, 2sp^3\right)$, the total energy donation to each bond with which it participates in bonding as it forms the terminal bond. The Coulombic energy $E_{Coulomb}\left(MO.atom, msp^3\right)$ of the outer electron of the *atom* msp^3 shell is given by Eq. (15.19). In the case that during hybridization, at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E(magnetic)$ (Eq. (15.15)) at the initial radius r of the AO electron. Then, the energy $E\left(MO.atom, msp^3\right)$ of the outer electron of the *atom* msp^3 shell is given by the sum of $E_{Coulomb}\left(MO.atom, msp^3\right)$ and $E(magnetic)$ (Eq. (15.20)).

In the specific case of the terminal bonding of two carbon atoms, the c_2 factor of each carbon given by Eq. (15.71) is determined using the Coulombic energy $E_{Coulomb}\left(C-C\ C2sp^3\right)$ of the outer electron of the $C2sp^3$ shell given by Eq. (15.19) with the radius $r_{C-C\ C2sp^3}$ of each $C2sp^3$ HO of the terminal $C-C$ bond calculated using Eq. (15.32) by considering $\sum E_{T_{mol}}\left(MO, 2sp^3\right)$, the total energy donation to each bond with which it participates in bonding as it forms the terminal bond including the contribution of the methylene energy, $0.92918\ eV$ (Eq. (14.513)), corresponding to the terminal $C-C$ bond. The corresponding $E_T\left(atom-atom, msp^3.AO\right)$ in Eq. (15.99) is $E_T\left(C-C\ C2sp^3\right) = -1.85836\ eV$.

In the case that the terminal atoms are carbon or other heteroatoms, the terminal bond comprises a linear combination of the HOs or AOs; thus, c_2' is the average of the hybridization factors of the participating atoms corresponding to the normalized linear sum:

$$c_2' = \frac{1}{2}\left(c_2'\left(atom\ 1\right) + c_2'\left(atom\ 2\right)\right) \tag{15.102}$$

In the exemplary cases of $C-C$, $O-O$, and $N-N$ where C is carbon:

$$\begin{aligned} c_2' &= \frac{1}{2}\left(\frac{\dfrac{e^2}{8\pi\varepsilon_0 a_0}}{\dfrac{e^2}{8\pi\varepsilon_0 r_{A-A\ A_1AO/HO}}} + \frac{\dfrac{e^2}{8\pi\varepsilon_0 a_0}}{\dfrac{e^2}{8\pi\varepsilon_0 r_{A-A\ A_2AO/HO}}}\right) \\ &= \frac{1}{2}\left(\frac{13.605804\ eV}{E_{Coulomb}\left(A-A.A_1AO/HO\right)} + \frac{13.605804\ eV}{E_{Coulomb}\left(A-A.A_2AO/HO\right)}\right) \end{aligned} \tag{15.103}$$

In the exemplary cases of $C-N$, $C-O$, and $C-S$,

$$c_2' = \frac{1}{2}\left(\frac{13.605804\ eV}{E_{Coulomb}\left(C-B\ C2sp^3\right)} + c_2\left(C\ to\ B\right)\right) \tag{15.104}$$

where C is carbon and $c_2\left(C\ to\ B\right)$ is the hybridization factor of Eqs. (15.61) and (15.93) that matches the energy of the atom B to that of the atom C in the group. For these cases, the corresponding $E_T\left(atom-atom, msp^3.AO\right)$ term in Eq. (15.99) depends on the hybridization and bond order of the terminal atoms in the molecule, but typical values matching those used in the determination of the bond energies (Eq. (15.65)) are:

$E_T\left(C-O\ C2sp^3.O2p\right) = -1.44915\ eV$; $E_T\left(C-O\ C2sp^3.O2p\right) = -1.65376\ eV$; $E_T\left(C-N\ C2sp^3.N2p\right) = -1.44915\ eV$;

$E_T\left(C-S\ C2sp^3.S2p\right) = -0.72457\ eV$; $E_T\left(O-O\ O2p.O2p\right) = -1.44915\ eV$; $E_T\left(O-O\ O2p.O2p\right) = -1.65376\ eV$;

$E_T\left(N-N\ N2p.N2p\right) = -1.44915\ eV$; $E_T\left(N-O\ N2p.O2p\right) = -1.44915\ eV$; $E_T\left(F-F\ F2p.F2p\right) = -1.44915\ eV$;

$E_T\left(Cl-Cl\ Cl3p.Cl3p\right) = -0.92918\ eV$; $E_T\left(Br-Br\ Br4p.Br4p\right) = -0.92918\ eV$; $E_T\left(I-I\ I5p.I5p\right) = -0.36229\ eV$;

$E_T\left(C-F\ C2sp^3.F2p\right)=-1.85836\ eV$; $E_T\left(C-Cl\ C2sp^3.Cl3p\right)=-0.92918\ eV$; $E_T\left(C-Br\ C2sp^3.Br4p\right)=-0.72457\ eV$; $E_T\left(C-I\ C2sp^3.I5p\right)=-0.36228\ eV$, and $E_T\left(O-Cl\ O2p.Cl3p\right)=-0.92918\ eV$.

In the case that the terminal bond is $X-X$ where X is a halogen atom, c_1 is one, and c_2' is the average (Eq. (15.102)) of the hybridization factors of the participating halogen atoms given by Eqs. (15.71-15.72) where $E_{Coulomb}\left(MO.atom,msp^3\right)$ is determined using Eq. (15.32) and $E_{Coulomb}\left(MO.atom,msp^3\right)=13.605804\ eV$ for $X=I$. The factor C_1 of Eq. (15.99) is one for all halogen atoms. The factor C_2 of fluorine is one since it is the only halogen wherein the ionization energy is greater than $13.605804\ eV$, the magnitude of the Coulombic energy between the electron and proton of H given by Eq. (1.264). For each of the other halogens, Cl, Br, and I, C_2 is the hybridization factor of Eq. (15.61) given by Eq. (15.79) with $c_2(1)$ being that of the halogen given by Eq. (15.77) that matches the valence energy of X ($E_1\left(valence\right)$) to that of the $C2sp^3$ HO ($E_2\left(valence\right)=-14.63489\ eV$, Eq. (15.25)) and to the hybridization of $C2sp^3$ HO ($c_2(2)=0.91771$, Eq. (13.430)). $E_T\left(atom-atom,msp^3.AO\right)$ of Eq. (15.99) is the maximum for the participating atoms which is $-1.44915\ eV$, $-0.92918\ eV$, $-0.92918\ eV$, and $-0.33582\ eV$ for F, Cl, Br, and I, respectively.

Consider the case that the terminal bond is $C-X$ where C is a carbon atom and X is a halogen atom. The factors c_1 and C_1 of Eq. (15.99) are one for all halogen atoms. For $X=F$, c_2' is the average (Eq. (15.104)) of the hybridization factors of the participating carbon and F atoms where c_2 for carbon is given by Eq. (15.71) and c_2 for fluorine matched to carbon is given by Eq. (15.79) with $c_2(1)$ for the fluorine atom given by Eq. (15.77) that matches the valence energy of F ($E_1\left(valence\right)=-17.42282\ eV$) to that of the $C2sp^3$ HO ($E_2\left(valence\right)=-14.63489\ eV$, Eq. (15.25)) and to the hybridization of $C2sp^3$ HO ($c_2(2)=0.91771$, Eq. (13.430)). The factor C_2 of fluorine is one since it is the only halogen wherein the ionization energy is greater than $13.605804\ eV$, the magnitude of the Coulombic energy between the electron and proton of H given by Eq. (1.264). For each of the other halogens, Cl, Br, and I, c_2' is the hybridization factor of the participating carbon atom since the halogen atom is energy matched to the carbon atom. C_2 of the terminal-atom bond matches that used to determine the energies of the corresponding $C-X$-bond MO. Then, C_2 is the hybridization factor of Eq. (15.61) given by Eq. (15.79) with $c_2(1)$ for the halogen atom given by Eq. (15.77) that matches the valence energy of X ($E_1\left(valence\right)$) to that of the $C2sp^3$ HO ($E_2\left(valence\right)=-14.63489\ eV$, Eq. (15.25)) and to the hybridization of $C2sp^3$ HO ($c_2(2)=0.91771$, Eq. (13.430)). $E_T\left(atom-atom,msp^3.AO\right)$ of Eq. (15.99) is the maximum for the participating atoms which is $-1.85836\ eV$, $-0.92918\ eV$, $-0.72457\ eV$, and $-0.33582\ eV$ for F, Cl, Br, and I, respectively.

Consider the case that the terminal bond is $H-X$ corresponding to the angle of the atoms HCX where C is a carbon atom and X is a halogen atom. The factors c_1 and C_1 of Eq. (15.99) are 0.75 for all halogen atoms. For $X=F$, c_2' is given by Eq. (15.78) with c_2 of the participating carbon and F atoms given by Eq. (15.71) and Eq. (15.74), respectively. The factor C_2 of fluorine is one since it is the only halogen wherein the ionization energy is greater than $13.605804\ eV$, the magnitude of the Coulombic energy between the electron and proton of H given by Eq. (1.264). For each of the other halogens, Cl, Br, and I, c_2' is also given by Eq. (15.78) with c_2 of the participating carbon given by Eq. (15.71) and c_2 of the participating X atom given by $c_2=0.91771$ (Eq. (13.430)) since the X atom is energy matched to the $C2sp^3$ HO. In these cases, C_2 is given by Eq. (15.74) for the corresponding atom X where C_2 matches the energy of the atom X to that of H.

Using the distance between the two atoms A and B of the general molecular group ACB when the total energy of the corresponding $A-B$ MO is zero, the corresponding bond angle can be determined from the law of cosines:

$$s_1^{\,2}+s_2^{\,2}-2s_1s_2\cos\theta=s_3^{\,2} \tag{15.105}$$

With $s_1=2c'_{C-A}$, the internuclear distance of the $C-A$ bond, $s_2=2c'_{C-B}$, the internuclear distance of each $C-B$ bond, and $s_3=2c'_{A-B}$, the internuclear distance of the two terminal atoms, the bond angle $\theta_{\angle ACB}$ between the $C-A$ and $C-B$ bonds is given by:

$$\left(2c'_{C-A}\right)^2+\left(2c'_{C-B}\right)^2-2\left(2c'_{C-A}\right)\left(2c'_{C-B}\right)\cos\theta=\left(2c'_{A-B}\right)^2 \tag{15.106}$$

$$\theta_{\angle ACB}=\cos^{-1}\left(\frac{\left(2c'_{C-A}\right)^2+\left(2c'_{C-B}\right)^2-\left(2c'_{A-B}\right)^2}{2\left(2c'_{C-A}\right)\left(2c'_{C-B}\right)}\right) \tag{15.107}$$

Consider the exemplary structure $C_bC_a(O_a)O_b$ wherein C_a is bound to C_b, O_a, and O_b. In the general case that the three bonds are coplanar and two of the angles are known, say θ_1 and θ_2, then the third θ_3 can be determined geometrically:

$$\theta_3 = 360 - \theta_1 - \theta_2 \tag{15.108}$$

In the general case that two of the three coplanar bonds are equivalent and one of the angles is known, say θ_1, then the second and third can be determined geometrically:

$$\theta_2 = \theta_3 = \frac{(360 - \theta_1)}{2} \tag{15.109}$$

ANGLES AND DISTANCES FOR AN MO THAT FORMS AN ISOSCELES TRIANGLE

In the general case where the group comprises three $A-B$ bonds having B as the central atom at the apex of a pyramidal structure formed by the three bonds with the A atoms at the base in the xy-plane, the C_{3v} axis centered on B is defined as the vertical or z-axis, and any two $A-B$ bonds form an isosceles triangle. Then, the angle of the bonds and the distances from and along the z-axis are determined from the geometrical relationships given by Eqs. (13.412-13.416).

the distance $d_{origin-B}$ from the origin to the nucleus of a terminal B atom is given by

$$d_{origin-B} = \frac{2c'_{B-B}}{2\sin 60°} \tag{15.110}$$

the height along the z-axis from the origin to the A nucleus d_{height} is given by:

$$d_{height} = \sqrt{\left(2c'_{A-B}\right)^2 - \left(d_{origin-B}\right)^2}\text{, and} \tag{15.111}$$

the angle θ_v of each $A-B$ bond from the z-axis is given by:

$$\theta_v = \tan^{-1}\left(\frac{d_{origin-B}}{d_{height}}\right) \tag{15.112}$$

Consider the case where the central atom B is further bound to a fourth atom C and the $B-C$ bond is along the z-axis. Then, the bond $\theta_{\angle ABC}$ given by Eq. (14.206) is:

$$\theta_{\angle ABC} = 180 - \theta_v \tag{15.113}$$

DIHEDRAL ANGLE

Consider the plane defined by a general ACA MO comprising a linear combination of two $C-A$-bond MOs where C is the central atom. The dihedral angle $\theta_{\angle BC/ACA}$ between the ACA-plane and a line defined by a third bond with C, specifically that corresponding to a $C-B$-bond MO, is calculated from the bond angle $\theta_{\angle ACA}$ and the distances between the A, B, and C atoms. The distance d_1 along the bisector of $\theta_{\angle ACA}$ from C to the internuclear-distance line between A and A, $2c'_{A-A}$, is given by:

$$d_1 = 2c'_{C-A}\cos\frac{\theta_{\angle ACA}}{2} \tag{15.114}$$

where $2c'_{C-A}$ is the internuclear distance between A and C. The atoms A, A, and B define the base of a pyramid. Then, the pyramidal angle $\theta_{\angle ABA}$ can be solved from the internuclear distances between A and A, $2c'_{A-A}$, and between A and B, $2c'_{A-B}$, using the law of cosines (Eq. (15.107)):

$$\theta_{\angle ABA} = \cos^{-1}\left(\frac{\left(2c'_{A-B}\right)^2 + \left(2c'_{A-B}\right)^2 - \left(2c'_{A-A}\right)^2}{2\left(2c'_{A-B}\right)\left(2c'_{A-B}\right)}\right) \tag{15.115}$$

Then, the distance d_2 along the bisector of $\theta_{\angle ABA}$ from B to the internuclear-distance line $2c'_{A-A}$, is given by:

$$d_2 = 2c'_{A-B}\cos\frac{\theta_{\angle ABA}}{2} \tag{15.116}$$

The lengths d_1, d_2, and $2c'_{C-B}$ define a triangle wherein the angle between d_1 and the internuclear distance between B and C, $2c'_{C-B}$, is the dihedral angle $\theta_{\angle BC/ACA}$ that can be solved using the law of cosines (Eq. (15.107)):

$$\theta_{\angle BC/ACA} = \cos^{-1}\left(\frac{d_1^2 + \left(2c'_{C-B}\right)^2 - d_2^2}{2d_1\left(2c'_{C-B}\right)}\right) \tag{15.117}$$

GENERAL DIHEDRAL ANGLE

Consider the plane defined by a general ACB MO comprising a linear combination of $C-A$ and $C-B$-bond MOs where C is the central atom. The dihedral angle $\theta_{\angle CD/ACB}$ between the ACB-plane and a line defined by a third bond of C with D, specifically that corresponding to a $C-D$-bond MO, is calculated from the bond angle $\theta_{\angle ACB}$ and the distances between the A, B, C, and D atoms. The distance d_1 from C to the bisector of the internuclear-distance line between A and B, $2c'_{A-B}$, is

given by two equations involving the law of cosines (Eq. (15.105)). One with $s_1 = 2c'_{C-A}$, the internuclear distance of the $C-A$ bond, $s_2 = d_1$, $s_3 = \frac{2c'_{A-B}}{2}$, half the internuclear distance between A and B, and $\theta = \theta_{\angle ACd_1}$, the angle between d_1 and the $C-A$ bond is given by:

$$\left(2c'_{C-A}\right)^2 + \left(d_1\right)^2 - 2\left(2c'_{C-A}\right)\left(d_1\right)\text{cosine}\,\theta_{\angle ACd_1} = \left(\frac{2c'_{A-B}}{2}\right)^2 \tag{15.118}$$

The other with $s_1 = 2c'_{C-B}$, the internuclear distance of the $C-B$ bond, $s_2 = d_1$, $s_3 = \frac{2c'_{A-B}}{2}$, and $\theta = \theta_{\angle ACB} - \theta_{\angle ACd_1}$ where $\theta_{\angle ACB}$ is the bond angle between the $C-A$ and $C-B$ bonds is given by:

$$\left(2c'_{C-B}\right)^2 + \left(d_1\right)^2 - 2\left(2c'_{C-B}\right)\left(d_1\right)\text{cosine}\left(\theta_{\angle ACB} - \theta_{\angle ACd_1}\right) = \left(\frac{2c'_{A-B}}{2}\right)^2 \tag{15.119}$$

Subtraction of Eq. (15.119) from Eq. (15.118) gives:

$$d_1 = \frac{\left(2c'_{C-A}\right)^2 - \left(2c'_{C-B}\right)^2}{2\left(\left(2c'_{C-A}\right)\text{cosine}\,\theta_{\angle ACd_1} - \left(2c'_{C-B}\right)\text{cosine}\left(\theta_{\angle ACB} - \theta_{\angle ACd_1}\right)\right)} \tag{15.120}$$

Substitution of Eq. (15.120) into Eq. (15.118) gives

$$\left(\begin{array}{l} \left(2c'_{C-A}\right)^2 + \left(\frac{\left(2c'_{C-A}\right)^2 - \left(2c'_{C-B}\right)^2}{2\left(\left(2c'_{C-A}\right)\text{cosine}\,\theta_{\angle ACd_1} - \left(2c'_{C-B}\right)\text{cosine}\left(\theta_{\angle ACB} - \theta_{\angle ACd_1}\right)\right)}\right)^2 \\ -2\left(2c'_{C-A}\right)\left(\frac{\left(2c'_{C-A}\right)^2 - \left(2c'_{C-B}\right)^2}{2\left(\left(2c'_{C-A}\right)\text{cosine}\,\theta_{\angle ACd_1} - \left(2c'_{C-B}\right)\text{cosine}\left(\theta_{\angle ACB} - \theta_{\angle ACd_1}\right)\right)}\right)\text{cosine}\,\theta_{\angle ACd_1} \\ -\left(\frac{2c'_{A-B}}{2}\right)^2 \end{array}\right) = 0 \tag{15.121}$$

The angle between d_1 and the $C-A$ bond, $\theta_{\angle ACd_1}$, can be solved reiteratively using Eq. (15.121), and the result can be substituted into Eq. (15.120) to give d_1.

The atoms A, B, and D define the base of a pyramid. Then, the pyramidal angle $\theta_{\angle ADB}$ can be solved from the internuclear distances between A and D, $2c'_{A-D}$, between B and D, $2c'_{B-D}$, and between A and B, $2c'_{A-B}$, using the law of cosines (Eq. (15.107)):

$$\theta_{\angle ADB} = \cos^{-1}\left(\frac{\left(2c'_{A-D}\right)^2 + \left(2c'_{B-D}\right)^2 - \left(2c'_{A-B}\right)^2}{2\left(2c'_{A-D}\right)\left(2c'_{B-D}\right)}\right) \tag{15.122}$$

Then, the distance d_2 from D to the bisector of the internuclear-distance line between A and B, $2c'_{A-B}$, is given by two equations involving the law of cosines (Eq. (15.105)). One with $s_1 = 2c'_{A-D}$, the internuclear distance between A and D, $s_2 = d_2$, $s_3 = \frac{2c'_{A-B}}{2}$, half the internuclear distance between A and B, and $\theta = \theta_{\angle ADd_2}$, the angle between d_2 and the $A-D$ axis is given by:

$$\left(2c'_{A-D}\right)^2 + \left(d_2\right)^2 - 2\left(2c'_{A-D}\right)\left(d_2\right)\text{cosine}\,\theta_{\angle ADd_2} = \left(\frac{2c'_{A-B}}{2}\right)^2 \tag{15.123}$$

The other with $s_1 = 2c'_{B-D}$, the internuclear distance between B and D, $s_2 = d_2$, and $\theta = \theta_{\angle ADB} - \theta_{\angle ADd_2}$ where $\theta_{\angle ADB}$ is the bond angle between the $A-D$ and $B-D$ axes is given by:

$$\left(2c'_{B-D}\right)^2 + \left(d_2\right)^2 - 2\left(2c'_{B-D}\right)\left(d_2\right)\text{cosine}\left(\theta_{\angle ADB} - \theta_{\angle ADd_2}\right) = \left(\frac{2c'_{A-B}}{2}\right)^2 \tag{15.124}$$

Subtraction of Eq. (15.124) from Eq. (15.123) gives:

$$d_2 = \frac{\left(2c'_{A-D}\right)^2 - \left(2c'_{B-D}\right)^2}{2\left(\left(2c'_{A-D}\right)\text{cosine}\,\theta_{\angle ADd_2} - \left(2c'_{B-D}\right)\text{cosine}\left(\theta_{\angle ADB} - \theta_{\angle ADd2}\right)\right)} \tag{15.125}$$

Substitution of Eq. (15.125) into Eq. (15.123) gives:

$$\left(\begin{array}{l}\left(2c'_{A-D}\right)^2+\left(\dfrac{\left(2c'_{A-D}\right)^2-\left(2c'_{B-D}\right)^2}{2\left(\left(2c'_{A-D}\right)\text{cosine}\theta_{\angle ADd_2}-\left(2c'_{B-D}\right)\text{cosine}\left(\theta_{\angle ADB}-\theta_{\angle ADd_2}\right)\right)}\right)^2 \\ -2\left(2c'_{A-D}\right)\left(\dfrac{\left(2c'_{A-D}\right)^2-\left(2c'_{B-D}\right)^2}{2\left(\left(2c'_{A-D}\right)\text{cosine}\theta_{\angle ADd_2}-\left(2c'_{B-D}\right)\text{cosine}\left(\theta_{\angle ADB}-\theta_{\angle ADd_2}\right)\right)}\right)\text{cosine}\theta_{\angle ADd_2} \\ -\left(\dfrac{2c'_{A-B}}{2}\right)^2\end{array}\right)=0 \tag{15.126}$$

The angle between d_2 and the $A-D$ axis, $\theta_{\angle ADd_2}$, can be solved reiteratively using Eq. (15.126), and the result can be substituted into Eq. (15.125) to give d_2.

The lengths d_1, d_2, and $2c'_{C-B}$ define a triangle wherein the angle between d_1 and the internuclear distance between C and D, $2c'_{C-D}$, is the dihedral angle $\theta_{\angle CD/ACB}$ that can be solved using the law of cosines (Eq. (15.107)):

$$\theta_{\angle CD/ACB}=\cos^{-1}\left(\frac{d_1^2+\left(2c'_{C-D}\right)^2-d_2^2}{2d_1\left(2c'_{C-D}\right)}\right) \tag{15.127}$$

SOLUTION OF GEOMETRICAL AND ENERGY PARAMETERS OF MAJOR FUNCTIONAL GROUPS AND CORRESPONDING ORGANIC MOLECULES

The exemplary molecules given in the following sections were solved using the solutions of organic chemical functional groups as basis elements wherein the structures and energies where linearly added to achieve the molecular solutions. Each functional group can be treated as a building block to form any desired molecular solution from the corresponding linear combination. Each functional group element was solved using the atomic orbital and hybrid orbital spherical atomic orbital solutions bridged by molecular orbitals comprised of the H_2-type prolate spheroidal solution given in the Nature of the Chemical Bond of Hydrogen-Type Molecules section. The energy of each MO was matched at the HO or AO by matching the hybridization and total energy of the MO to the AOs and HOs. The energy E_{mag} (e.g. given by Eq. (15.67) for a $C2sp^3$ HO and Eq. (15.68) for an $O2p$ AO) was subtracted for each set of unpaired electrons created by bond breakage.

The bond energy is not equal to the component energy of each bond as it exists in the molecule, although, they are close. The total energy of each group is its contribution to the total energy of the molecule as a whole. The determination of the bond energies for the creation of the separate parts must take into account the energy of the formation of any radicals and any redistribution of charge density within the pieces and the corresponding energy change with bond cleavage. Also, the vibrational energy in the transition state is dependent on the other groups that are bound to a given functional group. This will affect the functional-group energy. But, because the variations in the energy based on the balance of the molecular composition are typically of the order of a few hundreds of electron volts at most, they were neglected.

The energy of each functional-group MO bonding to a given carbon HO is independently matched to the HO by subtracting the contribution to the change in the energy of the HO from the total MO energy given by the sum of the MO contributions and $E\left(C,2sp^3\right)=-14.63489\,eV$ (Eq. (13.428)). The intercept angles are determined from Eqs. (15.80-15.87) using the final radius of the HO of each atom. The final carbon-atom radius is determined using Eqs. (15.32) wherein the sum of the energy contributions of each atom to all the MOs in which it participates in bonding is determined. This final radius is used in Eqs. (15.19) and (15.20) to calculate the final valence energy of the HO of each atom at the corresponding final radius. The radius of any bonding heteroatom that contributes to a MO is calculated in the same manner, and the energy of its outermost shell is matched to that of the MO by the hybridization factor between the carbon-HO energy and the energy of the heteroatomic shell. The donation of electron density to the AOs and HOs reduces the energy. The donation of the electron density to the MO's at each AO or HO is that which causes the resulting energy to be divided equally between the participating AOs or HOs to achieve energy matching.

The molecular solutions can be used to design synthetic pathways and predict product yields based on equilibrium constants calculated from the heats of formation. New stable compositions of matter can be predicted as well as the structures of combinatorial chemistry reactions. Further important pharmaceutical applications include the ability to graphically or computationally render the structures of drugs that permit the identification of the biologically active parts of the molecules to be identified from the common spatial charge-density functions of a series of active molecules. Drugs can be designed according to geometrical parameters and bonding interactions with the data of the structure of the active site of the drug.

To calculate conformations, folding, and physical properties, the exact solutions of the charge distributions in any given molecule are used to calculate the fields, and from the fields, the interactions between groups of the same molecule or between groups on different molecules are calculated wherein the interactions are distance and relative orientation dependent. The fields and interactions can be determined using a finite-element-analysis approach of Maxwell's equations.

CONTINUOUS-CHAIN ALKANES ($C_nH_{2n+2},\ n=3,4,5...\infty$)

The continuous-chain alkanes, C_nH_{2n+2}, are the homologous series comprising terminal methyl groups at each end of the chain with $n-2$ methylene (CH_2) groups in between:

$$CH_3(CH_2)_{n-2}CH_3 \tag{15.128}$$

C_nH_{2n+2} can be solved using the same principles as those used to solve ethane and ethylene wherein the $2s$ and $2p$ shells of each C hybridize to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. Three H AOs combine with three carbon $2sp^3$ HOs and two H AOs combine with two carbon $2sp^3$ HOs to form each methyl and methylene group, respectively, where each bond comprises a H_2-type MO developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section. The CH_3 and CH_2 groups bond by forming H_2-type MOs between the remaining $C2sp^3$ HOs on the carbons such that each carbon forms four bonds involving its four $C2sp^3$ HOs. For the alkyl $C-C$ group, $E_T\left(atom-atom,msp^3.AO\right)$ is $-1.85836\,eV$ where both energy contributions are given by Eq. (14.513). It is based on the energy match between the $C2sp^3$ HOs of the chain comprising methylene groups and terminal methyl groups.

The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of straight-chain alkanes are given in Tables 15.4, 15.5, and 15.6, respectively. The total energy of each straight-chain alkane given in Table 15.7 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.6 corresponding to functional-group composition of the molecule. The bond angle parameters of straight-chain alkanes determined using Eqs. (15.88-15.117) are given in Table 15.8. In this angle table and those given in subsequent sections when c_2' is given as the ratio of two values of c_2 designated to Atom 1 and Atom 2 and corresponding to $E_{Coulombic}$ of Atom 1 and Atom 2, respectively, then $c_2'=\dfrac{c_2(Atom\ 2)}{c_2(Atom\ 1)}$. The color scale, translucent view of the charge-density of exemplary alkane, butane comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.1.

Figure 15.1. (A-B) Color scale, translucent and opaque views of the charge-density of butane. Each representation shows the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

BRANCHED ALKANES ($C_nH_{2n+2},\ n=3,4,5...\infty$)

The branched-chain alkanes, C_nH_{2n+2}, comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-alkane groups are solved using the same principles as those used to solve the methyl and methylene functional groups wherein the $2s$ and $2p$ AOs of each C hybridize to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ HOs to form a MO permits each participating hybridized orbital to decrease in radius and energy. $E_T\left(atom-atom,msp^3.AO\right)$ of each $C-C$-bond MO in Eq. (15.61) due to the charge donation from the C atoms to the MO is $-1.85836\,eV$ or $-1.44915\,eV$ based on the energy match between the $C2sp^3$ HOs corresponding to the energy contributions equivalent to those of methylene, $-0.92918\,eV$ (Eq. (14.513)), or methyl, $-0.72457\,eV$ (Eq. (14.151)), groups, respectively.

The symbols of the functional groups of branched-chain alkanes are given in Table 15.9. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of branched-chain alkanes are given in Tables 15.10, 15.11, and 15.12, respectively. The total energy of each branched-chain alkane given in Table 15.13 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.12 corresponding to functional-group composition of the molecule. The bond angle parameters of branched-chain alkanes determined using Eqs. (15.88-15.117) are given in Table 15.14. The color scale, translucent view of the charge-density of exemplary alkane, isobutane, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.2.

Figure 15.2. Color scale, translucent view of the charge-density of isobutane showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (A) Top view. (B) Side view.

ALKENES (C_nH_{2n}, $n=3,4,5...\infty$)

The straight and branched-chain alkenes, C_nH_{2n}, comprise at least one carbon-carbon double bond comprising a functional group that is solved equivalently to the double bond of ethylene. The double bond may be bound to one, two, three, or four carbon single bonds that substitute for the hydrogen atoms of ethylene. Based on the condition of energy matching of the orbital, any magnetic energy due to unpaired electrons in the constituent fragments, and differences in oscillation in the transition state, three distinct functional groups can be identified: C vinyl single bond to $-C(C)=C$, C vinyl single bond to $-C(H)=C$, and C vinyl single bond to $-C(C)=CH_2$. In addition, CH_2 of the $-C=CH_2$ moiety is an alkene functional group.

The alkyl portion of the alkene may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkenes are equivalent to those in branched-chain alkanes. The solution of the functional groups comprises the hybridization of the $2s$ and $2p$ AOs of each C to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ HOs to form a MO permits each participating hybridized orbital to decrease in radius and energy. $E_T\left(atom-atom,msp^3.AO\right)$ of the $C=C$-bond MO in Eq. (15.61) due to the charge donation from the C atoms to the MO is equivalent to that of ethylene, $-2.26759\ eV$, given by Eq. (14.247). $E_T\left(atom-atom,msp^3.AO\right)$ of each $C-C$-bond MO in Eq. (15.61) is $-1.85836\ eV$ or $-1.44915\ eV$ based on the energy match between the $C2sp^3$ HOs corresponding to the energy contributions equivalent to those of methylene, $-0.92918\ eV$ (Eq. (14.513)), or methyl, $-0.72457\ eV$ (Eq. (14.151)), groups, respectively.

The symbols of the functional groups of alkenes are given in Table 15.15. The geometrical (Eqs. (15.1-15.5) and (15.41)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.56)) parameters of alkenes are given in Tables 15.16, 15.17, and 15.18, respectively. The total energy of each alkene given in Table 15.19 was calculated as the sum over the integer multiple of each $E_{D(Group)}$ of Table 15.18 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C2sp^3$ HO magnetic energy E_{mag} that is subtracted from the weighted sum of the $E_{D(Group)}$ (eV) values based on composition is given by Eq. (15.67). The bond angle parameters of alkenes, determined using Eqs. (15.88-15.117), are given in Table 15.20. The color scale, translucent view of the charge-density of exemplary alkene, propene, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.3.

Figure 15.3. Color scale, translucent view of the charge-density of propene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (A) Top view. (B) Side view.

Table 15.19. The total bond energies of alkenes calculated using the functional group composition and the energies of Table 15.18 compared to the experimental values [3]. The magnetic energy E_{mag} that is subtracted from the weighted sum of the $E_{D\,(Group)}$ (eV) values based on composition is given by (15.58).

ALKYNES (C_nH_{2n-2}, $n=3,4,5...\infty$)

The straight and branched-chain alkynes, C_nH_{2n-2}, have at least one carbon-carbon triple bond comprising a functional group that is solved equivalently to the triple bond of acetylene. The triple bond may be bound to one or two carbon single bonds that substitute for the hydrogen atoms of acetylene. Based on the energy matching of the mutually bound C, these $C-C$-bond MOs are defined as primary and secondary $C-C$ functional groups, respectively, that are unique to alkynes. In addition, the corresponding terminal CH of a primary alkyne comprises a functional group that is solved equivalently to the methylyne group of acetylene as given in the Acetylene Molecule section.

The alkyl portion of the alkyne may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkynes are equivalent to those in branched-chain alkanes.

The solution of the functional groups comprises the hybridization of the $2s$ and $2p$ AOs of each C to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ HOs to form a MO permits each participating hybridized orbital to decrease in radius and energy. $E_T\left(atom-atom,msp^3.AO\right)$ of the $C\equiv C$-bond MO in Eq. (15.61) due to the charge donation from the C atoms to the MO is equivalent to that of acetylene, $-3.13026\,eV$, given by Eq. (14.342). $E_T\left(atom-atom,msp^3.AO\right)$ of each -alkyl-bond MO in Eq. (15.61) is $-1.85836\,eV$ or $-1.44915\,eV$ based on the energy match between the $C2sp^3$ HOs corresponding to the energy contributions equivalent to those of methylene, $-0.92918\,eV$ (Eq. (14.513)), or methyl, $-0.72457\,eV$ (Eq. (14.151)), groups, respectively. For the $C-C$ groups each comprising a C single bond to $C\equiv C$, $E_T\left(atom-atom,msp^3.AO\right)$ is $-0.72457\,eV$ based on the energy match between the $C2sp^3$ HOs for the mutually bound C of the single and triple bonds. The parameter ω of each group is matched for oscillation in the transition state based on the group being primary or secondary.

The symbols of the functional groups of alkynes are given in Table 15.21. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkynes are given in Tables 15.22, 15.23, and 15.24, respectively. The total energy of each alkyne given in Table 15.25 is calculated as the sum over the integer multiple of each $E_{D(Group)}$ of Table 15.24 corresponding to functional-group composition of the molecule. The bond angle parameters of alkynes determined using Eqs. (15.88-15.117) are given in Table 15.26. Each C of the $C\equiv C$ group can further bond with only one atom, and the bond is linear as a minimum of energy as in the case of acetylene. The color scale, translucent view of the charge-density of exemplary alkyne, propyne, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.4.

Figure 15.4. Color scale, translucent view of the charge-density of propyne showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

ALKYL FLUORIDES ($C_nH_{2n+2-m}F_m,\ n=1,2,3,4,5...\infty\ m=1,2,3...\infty$)

The branched-chain alkyl fluorides, $C_nH_{2n+2-m}F_m$, may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds wherein at least one H is replaced by a fluorine. The $C-F$ bond comprises a functional group for each case of F replacing a H of methane in the series $H_{4-m}C-F_m$, $m=1,2,3,4$, and F replacing a H of an alkane. The methyl, methylene, methylyne functional groups are equivalent to those of branched-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups that are equivalent to those of branched-chain alkanes.

The solution of the $C-F$ functional groups comprises the hybridization of the $2s$ and $2p$ AOs of each C to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the F AO to form a molecular orbital (MO) permits each participating orbital to decrease in radius and energy. In alkyl fluorides, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)), and the F AO has an energy of $E(F)=-17.42282\ eV$. To meet the equipotential condition of the union of the $C-F$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.61) for the $C-F$-bond MO given by Eqs. (15.77) and (15.79) is:

$$c_2\left(C2sp^3HO\ to\ F\right)=\frac{E\left(C,2sp^3\right)}{E(F)}c_2\left(C2sp^3HO\right)=\frac{-14.63489\ eV}{-17.42282\ eV}(0.91771)=0.77087 \tag{15.129}$$

$E_T\left(atom-atom,msp^3.AO\right)$ of the $C-F$-bond MO in Eq. (15.61) based on the charge donation from F to the MO is determined by the linear combination that results in a energy that is a minimum which does not exceed the energy of the AO of the F atom to which it is energy matched.

The symbols of the functional groups of branched-chain alkyl fluorides are given in Table 15.27. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of branched-chain alkyl fluorides are given in Tables 15.28, 15.29, and 15.30, respectively. The total energy of each branched-chain alkyl fluoride given in Table 15.31 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.30 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C2sp^3$ HO magnetic energy E_{mag} that is subtracted from the weighted sum of the $E_D(Group)$ (eV) values based on composition is given by Eq. (15.67). In the case of trifluoromethane, E_{mag} is positive since the term due to the fluorine atoms cancels that of the CH group. The $C-C$ bonds to the CHF group (one H bond to C) were each treated as an iso $C-C$ bond. The $C-C$ bonds to the CF group (no H bonds to C) were each treated as a tert-butyl $C-C$. E_{mag} was subtracted for each t-butyl group. The bond angle parameters of branched-chain alkyl fluorides determined using Eqs. (15.70-15.79), (15.87-15.117) and (15.129) are given in Table 15.32. The color scale, translucent view of the charge-density of exemplary alkyl fluoride, 1-fluoropropane, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.5.

Figure 15.5. Color scale, translucent view of the charge-density of 1-fluoropropane showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

ALKYL CHLORIDES ($C_nH_{2n+2-m}Cl_m,\ n=1,2,3,4,5...\infty\ m=1,2,3...\infty$)

The branched-chain alkyl chlorides, $C_nH_{2n+2-m}Cl_m$, may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds wherein at least one H is replaced by a chlorine. The $C-Cl$ bond comprises a functional group for each case of Cl replacing a H of methane for the series $H_{4-m}C-Cl_m$, $m=1,2,3$, with the $C-Cl$ bond of CCl_4 comprising another functional group due to the limitation of the minimum energy of Cl matched to that of the $C2sp^3$ HO. In addition, the $C-Cl$ bond due to Cl replacing an H of an alkane is a functional group. The methyl, methylene, methylyne functional groups are equivalent to those of branched-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups that are equivalent to those of branched-chain alkanes.

The solution of the $C-Cl$ functional groups comprises the hybridization of the $2s$ and $2p$ AOs of each C to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the Cl AO to form a MO permits each participating orbital to decrease in radius and energy. In alkyl chlorides, the energy of chlorine is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264). Thus, c_2 in Eq. (15.61) is one, and the energy matching condition is determined by the C_2 parameter. Then, $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)), and the Cl AO has an energy of $E\left(Cl\right)=-12.96764\ eV$. To meet the equipotential condition of the union of the $C-Cl$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor C_2 of Eq. (15.61) for the $C-Cl$-bond MO given by Eqs. (15.77) and (15.79) is:

$$C_2\left(C2sp^3HO\ to\ Cl\right)=\frac{E\left(Cl\right)}{E\left(C,2sp^3\right)}c_2\left(C2sp^3HO\right)=\frac{-12.96764\ eV}{-14.63489\ eV}\left(0.91771\right)=0.81317 \tag{15.130}$$

The valence energy of the carbon $2p$ is $-11.2603\ eV$ and that of the Cl AO is $-12.96764\ eV$. The energy difference is more than that of $2E_T\left(C-C,2sp^3\right)$ given by Eq. (14.151) for a single bond. Thus, $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-Cl$-bond MO of CCl_mH_{4-m} and $C_nH_{2n+2-m}Cl_m$ in Eq. (15.61) due to the charge donation from the C and Cl atoms to the MO is $-1.44915\ eV$ based on the energy match between the $C2sp^3$ HO and the Cl AO corresponding to the energy contributions equivalent to those of methyl groups, $-0.72457\ eV$ (Eq. (14.151)). $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-Cl$-bond MO of chloroform with four $C-Cl$ bonds is $-0.92918\ eV$ (Eq. (14.513)) based on the maximum single-bond-energy contribution of the $C2sp^3$ HO.

The symbols of the functional groups of branched-chain alkyl chlorides are given in Table 15.33. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of branched-chain alkyl chlorides are given in Tables 15.34, 15.35, and 15.36, respectively. The total energy of each branched-chain alkyl chloride given in Table 15.37 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.36 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C2sp^3$ HO magnetic energy E_{mag} that was subtracted from the weighted sum of the $E_D(Group)$ (eV) values based on composition is given by Eq. (15.67). The $C-C$ bonds to the $CHCl$ group (one H bond to C) were each treated as an iso $C-C$ bond. The $C-C$ bonds to the CCl group (no H bonds to C) were each treated as a tert-butyl $C-C$. E_{mag} was subtracted for each t-butyl group. The bond angle parameters of branched-chain alkyl chlorides determined using Eqs. (15.70-15.79), (15.88-15.117) and (15.130) are given in Table 15.38. The color scale, translucent view of the charge-density of exemplary alkyl chloride, 1-chloropropane, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.6.

Figure 15.6. Color scale, translucent view of the charge-density of 1-chloropropane showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.37. The total bond energies of branched-chain alkyl chlorides calculated using the functional group composition and the energies of Table 15.36 compared to the experimental values [3]. The magnetic energy E_{mag} that is subtracted from the weighted sum of the $E_{D\,(Group)}$ (eV) values based on composition is given by (15.58).

ALKYL BROMIDES ($C_nH_{2n+2-m}Br_m,\ n=1,2,3,4,5...\infty\ \ m=1,2,3...\infty$)

The branched-chain alkyl bromides, $C_nH_{2n+2-m}Br_m$, may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds wherein at least one H is replaced by a bromine. The $C-Br$ bond comprises a functional group for each case of Br replacing a H of methane for the series $H_{4-m}C-Br_m,\ m=1,2,3,$ with the $C-Br$ bond of CBr_4 comprising another functional group due to the limitation of the minimum energy of Br matched to that of the $C2sp^3$ HO. In addition, the $C-Br$ bond due to Br replacing a H of an alkane is a functional group. The methyl, methylene, methylyne functional groups are equivalent to those of branched-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups that are equivalent to those of branched-chain alkanes.

The solution of the $C-Br$ functional groups comprises the hybridization of the $2s$ and $2p$ shells of each C to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ hybridized orbital (HO) and the Br AO to form a molecular orbital (MO) permits each participating orbital to decrease in radius and energy. In alkyl bromides, the energy of bromine is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264). Thus, c_2 in Eq. (15.61) is one, and the energy matching condition is determined by the C_2 parameter. Then, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)), and the Br AO has an energy of $E\left(Br\right)=-11.81381\ eV$. To meet the equipotential condition of the union of the $C-Br$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor C_2 of Eq. (15.61) for the $C-Br$-bond MO given by Eqs. (15.77) and (15.79) is:

$$C_2\left(C2sp^3HO\ to\ Br\right)=\frac{E\left(Br\right)}{E\left(C,2sp^3\right)}c_2\left(C2sp^3HO\right)=\frac{-11.81381\ eV}{-14.63489\ eV}\left(0.91771\right)=0.74081 \tag{15.131}$$

The valence energy of the carbon $2p$ is $-11.2603\ eV$ and that of the Br AO is $-11.81381\ eV$. The energy difference is less than that of $E_T\left(C-C,2sp^3\right)$ given by Eq. (14.151) for a single bond. Thus, $E_T\left(atom-atom,msp^3.AO\right)$ of the alkyl $C-Br$-bond MO in Eq. (15.61) due to the charge donation from the C and Br atoms to the MO is $-0.92918\ eV$ (Eq. (14.513)) based on the maximum single-bond-energy contribution of the $C2sp^3$ HO. $E_T\left(atom-atom,msp^3.AO\right)$ of the series $CBr_mH_{4-m}\ m=1,2,3$ is equivalent to those of methyl groups, $-0.72457\ eV$ (Eq. (14.151)). For CBr_4, $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-Br$-bond MO in Eq. (15.61) due to the charge donation from the C and Br atoms to the MO is $-0.36229\ eV$ based on the maximum charge density on the $C2sp^3$ HO. It is given by Eqs. (15.18-15.20) and Eq. (15.29) with a linear combination of $s=1$ corresponding to $E_T\left(atom-atom,msp^3.AO\right)=-0.72457\ eV$ and $s=0$ corresponding to: $E_T\left(atom-atom,msp^3.AO\right)=0$.

The symbols of the functional groups of branched-chain alkyl bromides are given in Table 15.39. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of branched-chain alkyl bromides are given in Tables 15.49, 15.50, and 15.51, respectively. The total energy of each branched-chain alkyl bromide given in Table 15.52 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.51 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C2sp^3$ HO magnetic energy E_{mag} that was subtracted from the weighted sum of the $E_{D\,(Group)}$ (eV) values based on composition is given by Eq. (15.67). The $C-C$ bonds to the $CHBr$ group (one H bond to C) were each treated as an iso $C-C$ bond. The $C-C$ bonds to the CBr group (no H bonds to C) were each treated as a tert-butyl $C-C$. The bond angle parameters of branched-chain alkyl bromides determined using Eqs. (15.70-15.79), (15.88-15.117) and (15.131) are given in Table 15.44. The color scale, translucent view of the charge-density of exemplary alkyl bromide, 1-bromopropane, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.7.

Figure 15.7. Color scale, translucent view of the charge-density of 1-bromopropane showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

ALKYL IODIDES ($C_nH_{2n+2-m}I_m,\ n=1,2,3,4,5...\infty\ m=1,2,3...\infty$)

The branched-chain alkyl iodides, $C_nH_{2n+2-m}I_m$, may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds wherein at least one H is replaced by an iodine atom. The $C-I$ bond comprises a functional group for I replacing a H of methane (CH_3I) or for I replacing a H of an alkane corresponding to the series $C_nH_{2n+2-m}I_m$. The $C-I$ bond of each of CH_2I_2 and CHI_3 comprise separate functional groups due to the limitation of the minimum energy of I matched to that of the $C2sp^3$ HO. The methyl, methylene, methylyne functional groups are equivalent to those of branched-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups that are equivalent to those of branched-chain alkanes.

The solution of the $C-I$ functional groups comprises the hybridization of the $2s$ and $2p$ AOs of each C to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the I AO to form a MO permits each participating orbital to decrease in radius and energy. In alkyl iodides, the energy of iodine is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264). Thus, c_2 in Eq. (15.61) is one, and the energy matching condition is determined by the C_2 parameter. Then, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)). The I AO has an energy of $E(I)=-10.45126\ eV$. To meet the equipotential condition of the union of the $C-I$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor C_2 of Eq. (15.60) for the $C-I$-bond MO given by Eqs. (15.77) and (15.79) is:

$$C_2\left(C2sp^3HO\ to\ I\right)=\frac{E(I)}{E\left(C,2sp^3\right)}c_2\left(C2sp^3HO\right)=\frac{-10.45126\ eV}{-14.63489\ eV}(0.91771)=0.65537 \tag{15.132}$$

The valence energy of the carbon $2p$ is $-11.2603\ eV$ and that of the I AO is $-10.45126\ eV$. The energy difference is positive. Thus, based on the maximum charge density on the $C2sp^3$ HO $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-I$-bond MO in Eq. (15.61) due to the charge donation from the C and I atoms to the MO is $-0.36229\ eV$ (Eqs. (15.18-15.20 and Eq. (15.29) with a linear combination of $s=1$, $E_T\left(atom-atom,msp^3.AO\right)=-0.72457\ eV$ and $E_T\left(atom-atom,msp^3.AO\right)=0$) for methyl and alkyl iodides, $-0.18114\ eV$ for diiodomethane, and 0 for CHI_3.

The symbols of the functional groups of branched-chain alkyl iodides are given in Table 15.45. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of branched-chain alkyl iodides are given in Tables 15.55, 15.56, and 15.57, respectively. The total energy of each branched-chain alkyl iodide given in Table 15.49 was calculated as the sum over the integer multiple of each $E_{D(Group)}$ of Table 15.48 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C2sp^3$ HO magnetic energy E_{mag} that was subtracted from the weighted sum of the $E_{D(Group)}$ (eV) values based on composition is given by Eq. (15.67). The $C-C$ bonds to the CHI group (one H bond to C) were each treated as an iso $C-C$ bond. The $C-C$ bonds to the CI group (no H bonds to C) were each treated as a tert-butyl $C-C$. E_{mag} is subtracted for each t-butyl group. The bond angle parameters of branched-chain alkyl iodides determined using Eqs. (15.70-15.79), (15.88-15.117) and (15.132) are given in Table 15.50. The color scale, translucent view of the charge-density of exemplary alkyl iodide, 1-iodopropane, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.8.

Figure 15.8. Color scale, translucent view of the charge-density of 1-iodopropane showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

ALKENYL HALIDES ($C_nH_{2n-m}X_m,\ n=3,4,5...\infty\ m=1,2,3...\infty$)

The branched-chain alkenyl halides, $C_nH_{2n+2-m}X_m$ with $X=F,Cl,Br,I$, may comprise alkyl and alkenyl functional groups wherein at least one H is replaced by a halogen atom. In the case that a halogen atom replaces an alkyl H, the $C-X$ bond comprises the alkyl-halogen functional groups given in their respective sections. The alkenyl halogen $C-X$ bond comprises a separate functional group for each case of X bonding to the $C=C$-bond functional group given in the Alkenes section. In addition the CH group of the moiety $XCH=C$ comprises a functional group unique to alkenyl halides. The straight and branched-chain alkenes, C_nH_{2n}, comprise at least one carbon-carbon double bond comprising a functional group that is solved equivalently to the double bond of ethylene. The double bond may be bound to one, two, three, or four carbon single bonds that substitute for the hydrogen atoms of ethylene. The three distinct functional groups given in the Alkenes section are C vinyl single bond to $-C(C)=C$, C vinyl single bond to $-C(H)=C$, and C vinyl single bond to $-C(C)=CH_2$. In addition, CH_2 of the $-C=CH_2$ moiety is also an alkene functional group solved in the Alkenes section.

Consider the case where $X=Cl$ substitutes for a carbon single bond or a hydrogen atom. Based on the condition of energy matching of the orbital, any magnetic energy due to unpaired electrons in the constituent fragments, and differences in oscillation in the transition state, two distinct $C-Cl$ functional groups can be identified: Cl vinyl single bond to $-C(C)=C$ and Cl vinyl single bond to $-C(H)=C$. The alkenyl-halide CH group is equivalent to that solved in the Hydrogen Carbide (CH) section except that $\Delta E_{H_2MO}\left(AO/HO\right)=-1.13379\ eV$ in order to energy match to the $C-Cl$ and $C=C$ bonds.

The alkyl portion of the alkenyl halide may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($\left(CH_3\right)_2CH$) and t-butyl ($\left(CH_3\right)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkene halides are equivalent to those in branched-chain alkanes.

$E_T\left(atom-atom,msp^3.AO\right)$ of the $C=C$-bond MO in Eq. (15.61) due to the charge donation from the C atoms to the MO is equivalent to that of ethylene, $-2.26759\ eV$, given by Eq. (14.247). $E_T\left(atom-atom,msp^3.AO\right)$ of each $C-C$-bond MO in Eq. (15.61) is $-1.85836\ eV$ or $-1.44915\ eV$ based on the energy match between the $C2sp^3$ HOs corresponding to the energy contributions equivalent to those of methylene, $-0.92918\ eV$ (Eq. (14.513), or methyl, $-0.72457\ eV$ (Eq. (14.151)), groups, respectively.

The solution of each $C-X$ functional group comprises the hybridization of the $2s$ and $2p$ AOs of the C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the X AO to form a MO permits each participating orbital to decrease in radius and energy. The alkenyl $C-X$-bond functional groups comprise single bonds and are equivalent to those of the corresponding alkyl halides except that the halogen AO and the $C-X$-bond MO are each energy matched to the alkene $C2sp^3$ HO. In alkenyl halides with $X=Cl,Br,\ or\ I$, the energy of the halogen atom is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264)). Thus, c_2 in Eq. (15.61) is one, and the energy matching condition is determined by the C_2 parameter. For example, the hybridization factor C_2 of Eq. (15.61) for the alkenyl $C-Cl$-bond MO given by Eq. (15.130) is $C_2\left(C2sp^3HO\ to\ \mathrm{Cl}\right)=0.81317$.

$E_T\left(atom-atom,msp^3.AO\right)$ of the alkenyl $C-Cl$-bond MO in Eq. (15.61) due to the charge donation from the C and Cl atoms to the MO is $-1.44915\ eV$ for the Cl vinyl single bond to $-C(H)=C\ \ C-Cl$ group and $-0.92918\ eV$ for the Cl vinyl single bond to $-C(C)=C\ \ C-Cl$ group. It is based on the energy match between the Cl atom and the $C2sp^3$ HO of an unsubstituted vinyl group and a substituted vinyl group given by Eqs. (14.151) and (14.513), respectively.

The symbols of the functional groups of branched-chain alkenyl chlorides are given in Table 15.51. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of branched-chain alkenyl chlorides are given in Tables 15.52, 15.53, and 15.54, respectively. The total energy of each branched-chain alkenyl chloride given in Table 15.55 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.54 corresponding to functional-group composition of the molecule. The bond angle parameters of branched-chain alkenyl chlorides determined using Eqs. (15.70-15.79), (15.88-15.117) and (15.130) are given in Table 15.56. The color scale, translucent view of the charge-density of exemplary alkenyl halide, 2-chloropropene, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.9.

Figure 15.9. Color scale, translucent view of the charge-density of 2-chloropropene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

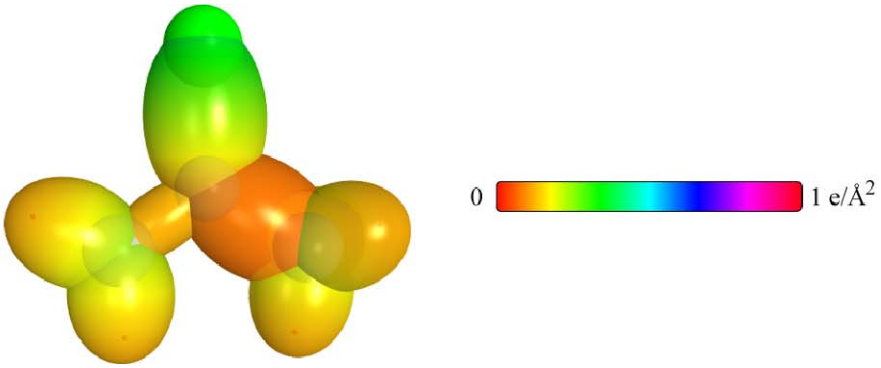

Table 15.51. The symbols of functional groups of branched-chain alkenyl chlorides.

Functional Group	Group Symbol
Cl vinyl single bond to -*C*(*H*)=*C*	$C-Cl$ (i)
Cl vinyl single bond to -*C*(*C*)=*C*	$C-Cl$ (ii)
CC double bond	$C=C$
C vinyl single bond to -*C*(*C*)=*C*	$C-C$ (i)
C vinyl single bond to -*C*(*H*)=*C*	$C-C$ (ii)
C vinyl single bond to -*C*(*C*))=CH_2	$C-C$ (iii)
CH (alkenyl halide)	$C-H$ (i)
CH_2 alkenyl group	$C-H\ (CH_2)$ (i)
CH_3 group	$C-H\ (CH_3)$
CH_2 alkyl group	$C-H\ (CH_2)$ (ii)
CH (alkyl)	$C-H$ (ii)
CC bond (*n*-*C*)	$C-C$ (a)
CC bond (*iso*-*C*)	$C-C$ (b)
CC bond (*tert*-*C*)	$C-C$ (c)
CC (*iso* to *iso*-*C*)	$C-C$ (d)
CC (*t* to *t*-*C*)	$C-C$ (e)
CC (*t* to *iso*-*C*)	$C-C$ (f)

ALCOHOLS ($C_nH_{2n+2}O_m,\ n=1,2,3,4,5...\infty$)

The alkyl alcohols, $C_nH_{2n+2}O_m$, comprise an OH functional group and two types of $C-O$ functional groups, one for methyl alcohol and the other for general alkyl alcohols. The alkyl portion of the alkyl alcohol may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alcohols are equivalent to those in branched-chain alkanes.

The OH functional group was solved in the Hydroxyl Radical (OH) section. Each $C-O$ group is solved by hybridizing the $2s$ and $2p$ AOs of the C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the O AO to form a MO permits each participating orbital to decrease in radius and energy. In alkyl alcohols, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E(C,2sp^3)=-14.63489\ eV$ (Eq. (15.25)) and the O AO has an energy of $E(O)=-13.61806\ eV$. To meet the equipotential condition of the union of the $C-O$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.61) for the $C-O$-bond MO given by Eqs. (15.77) and (15.79) is:

$$c_2\left(C2sp^3HO\ to\ O\right)=\frac{E(O)}{E\left(C,2sp^3\right)}c_2\left(C2sp^3HO\right)=\frac{-13.61806\ eV}{-14.63489\ eV}(0.91771)=0.85395 \tag{15.133}$$

$E_T\left(atom-atom,msp^3.AO\right)$ of the $C-O$-bond MO in Eq. (15.61) due to the charge donation from the C and O atoms to the MO is $-1.65376\ eV$ for the CH_3-OH $C-O$ group. It is based on the energy match between the OH group and the $C2sp^3$ HO of a methyl group and is given by the linear combination of $-0.92918\ eV$ (Eq. (14.513)) and $-0.72457\ eV$ (Eq. (14.151)), respectively. For the alkyl $C-O$ group, $E_T\left(atom-atom,msp^3.AO\right)$ is $-1.85836\ eV$. It is based on the energy match between the O AO and the $C2sp^3$ HO of a methylene group where both energy contributions are given by Eq. (14.513).

The symbols of the functional groups of branched-chain alkyl alcohols are given in Table 15.66. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl alcohols are given in Tables 15.58, 15.59, and 15.60, respectively. The total energy of each alkyl alcohol given in Table 15.61 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.60 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl alcohols determined using Eqs. (15.88-15.117) are given in Table 15.62. The color scale, translucent view of the charge-density of exemplary alcohol, 1-propanol, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.10.

Figure 15.10. Color scale, translucent view of the charge-density of 1-propanol showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (A) Side view. (B) Front view.

ETHERS ($C_nH_{2n+2}O_m,\ n=2,3,4,5...\infty$)

The alkyl ethers, $C_nH_{2n+2}O_m$, comprise two types of $C-O$ functional groups, one for methyl or t-butyl groups corresponding to the C and the other for general alkyl groups. The alkyl portion of the alkyl ether may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in ethers are equivalent to those in branched-chain alkanes.

Each $C-O$ group is solved by hybridizing the $2s$ and $2p$ AOs of the C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the O AO to form a MO permits each participating orbital to decrease in radius and energy. In alkyl ethers, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) and an energy of $E(C,2sp^3)=-14.63489\,eV$ (Eq. (15.25)) and the O AO has an energy of $E(O)=-13.61806\,eV$. To meet the equipotential condition of the union of the $C-O$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.61) for the $C-O$-bond MO given by Eq. (15.133) is $c_2(C2sp^3HO\ to\ O)=0.85395$. $E_T(atom-atom,msp^3.AO)$ of the $C-O$-bond MO in Eq. (15.52) due to the charge donation from the C and O atoms to the MO is $-1.44915\,eV$ for the CH_3-O- and $(CH_3)_3C-O-$ $C-O$ groups. It is based on the energy match between the O AO, initially at the Coulomb potential of a proton and an electron (Eqs. (1.257) and (10.162), respectively), and the $C2sp^3$ HO of a methyl group as given by Eq. (14.151). For the alkyl $C-O$ group, $E_T(atom-atom,msp^3.AO)$ is $-1.65376\,eV$. It is based on the energy match between the O AO and the $C2sp^3$ HO of a methylene group and is given by the linear combination of $-0.72457\,eV$ (Eq. (14.151)) and $-0.92918\,eV$ (Eq. (14.513)), respectively.

The symbols of the functional groups of branched-chain alkyl ethers are given in Table 15.63. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl ethers are given in Tables 15.64, 15.65, and 15.66, respectively. The total energy of each alkyl ether given in Table 15.67 was calculated as the sum over the integer multiple of each $E_{D(Group)}$ of Table 15.66 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl ethers determined using Eqs. (15.88-15.117) are given in Table 15.68. The color scale, translucent view of the charge-density of exemplary ether, diethyl ether, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.11.

Figure 15.11. Color scale, translucent view of the charge-density of diethyl ether showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (A) Oblique view. (B) View along the nitrogen atom.

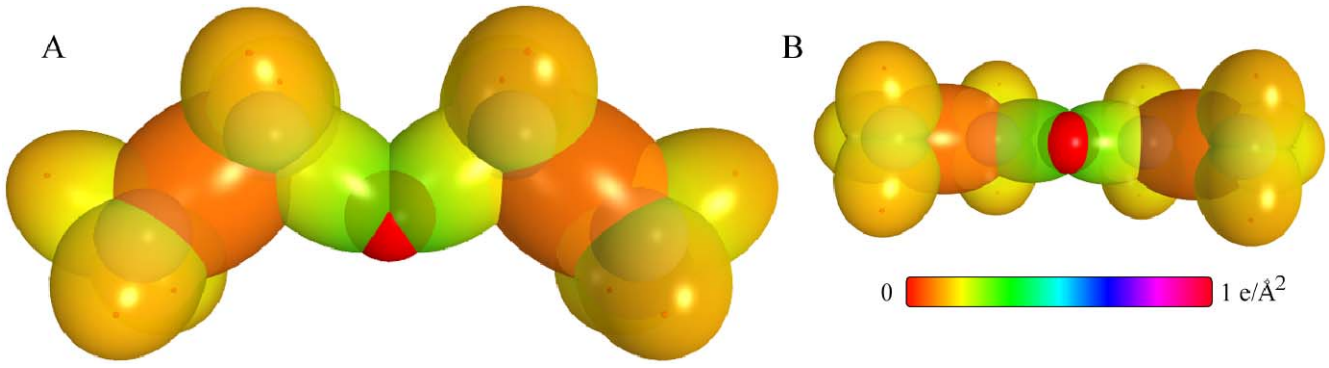

Table 15.63. The symbols of functional groups of alkyl ethers.

Functional Group	Group Symbol

PRIMARY AMINES ($C_nH_{2n+2+m}N_m,\ n=1,2,3,4,5...\infty$)

The primary amines, $C_nH_{2n+2+m}N_m$, comprise an NH_2 functional group and a $C-N$ functional group. The alkyl portion of the primary amine may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in primary amines are equivalent to those in branched-chain alkanes.

The primary amino (NH_2) functional group was solved using the procedure given in the Dihydrogen Nitride (NH_2) section. Using the results of Eqs. (13.245-13.368), the primary amino parameters in Eq. (15.61) are $n_1=2$, $C_1=0.75$, $C_2=0.93613$ (Eqs. (13.248-13.249)), $C_{1o}=1.5$, and $c_1=0.75$. In primary amines, the $C2sp^3$ HO of the $C-NH_2$-bond MO has an energy of $E\left(C,2sp^3\right)=-15.35946\ eV$ (Eq. (15.18) with $s=1$ and Eqs. (15.19-15.20)) and the N AO has an energy of $E(N)=-14.53414\ eV$. To meet the equipotential condition of the union of the $N-H$ H_2-type-ellipsoidal-MO with the $C2sp^3$ HO, the hybridization factor c_2 of Eq. (15.61) for the $N-H$-bond MO given by Eq. (15.77) is:

$$c_2\left(H\ to\ 1°N\right)=\frac{E(N)}{E\left(C,2sp^3\right)}=\frac{-14.53414\ eV}{-15.35946\ eV}=0.94627 \tag{15.134}$$

The $C-N$ group is solved by hybridizing the $2s$ and $2p$ AOs of the C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the N AO to form a MO permits each participating orbital to decrease in radius and energy. In primary amines, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)), and the N AO has an energy of $E(N)=-14.53414\ eV$. To meet the equipotential condition of the union of the $C-N$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.61) for the $C-N$-bond MO given by Eqs. (15.77) and (15.79) is:

$$c_2\left(C2sp^3HO\ to\ N\right)=\frac{E(N)}{E\left(C,2sp^3\right)}c_2\left(C2sp^3HO\right)=\frac{-14.53414\ eV}{-14.63489\ eV}(0.91771)=0.91140 \tag{15.135}$$

$E_T\left(atom-atom,msp^3.AO\right)$ of the $C-N$-bond MO in Eq. (15.61) due to the charge donation from the C and N atoms to the MO is $-1.44915\ eV$. It is based on the energy match between the N of the NH_2 group and the $C2sp^3$ HO corresponding to the energy contributions to the single bond that are equivalent to those of methyl groups, $-0.72457\ eV$ (Eq. (14.151)), where the $N-H$ bonds are also energy matched to the $C-N$ bond.

The symbols of the functional groups of branched-chain primary amines are given in Table 15.69. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of primary amines are given in Tables 15.70, 15.71, and 15.72, respectively. The total energy of each primary amine given in Table 15.73 was calculated as the sum over the integer multiple of each $E_{D(Group)}$ of Table 15.72 corresponding to functional-group composition of the molecule. The bond angle parameters of primary amines determined using Eqs. (15.88-15.117) are given in Table 15.74. The color scale, translucent view of the charge-density of exemplary primary amine, propylamine, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.12.

Figure 15.12. (A)-(B) Color scale, translucent views of the charge-density of propylamine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

SECONDARY AMINES ($C_nH_{2n+2+m}N_m,\ n=2,3,4,5...\infty$)

The secondary amines, $C_nH_{2n+2+m}N_m$, comprise an NH functional group and two types of $C-N$ functional groups, one for the methyl group corresponding to the C of $C-N$ and the other for general alkyl secondary amines. The alkyl portion of the secondary amine may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in secondary amines are equivalent to those in branched-chain alkanes.

The secondary amino (NH) functional group was solved using the procedure given in the Hydrogen Nitride (NH) section. Using the results of Eqs. (13.245-13.316), the secondary amino parameters in Eq. (15.61) are $n_1=1$, $C_1=0.75$, $C_2=0.93613$ (Eqs. (13.248-13.249)), $C_{1o}=0.75$, and $c_1=0.75$. In secondary amines, the $C2sp^3$ HO of the $C-NH$ -bond MO has an energy of $E\left(C,2sp^3\right)=-15.56407\ eV$ (Eqs. (14.514-14.516)); Eq. (15.29) with $s=1$ and $s=2$, Eq. (15.31), and Eqs. (15.19-15.20)) and the N AO has an energy of $E(N)=-14.53414\ eV$ (Eq. (13.251)). To meet the equipotential condition of the union of the $N-H$ H_2-type-ellipsoidal-MO with the $C2sp^3$ HO, the hybridization factor c_2 of Eq. (15.61) for the $N-H$ -bond MO given by Eq. (15.77) is:

$$c_2\left(H\ to\ 2°N\right)=\frac{E(N)}{E\left(C,2sp^3\right)}=\frac{-14.53414\ eV}{-15.56407\ eV}=0.93383 \tag{15.136}$$

The $C-N$ group is solved by hybridizing the $2s$ and $2p$ AOs of the C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the N AO to form a MO permits each participating orbital to decrease in radius and energy. In secondary amines, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)), and the N AO has an energy of $E(N)=-14.53414\ eV$. To meet the equipotential condition of the union of the $C-N$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.61) for the $C-N$ -bond MO given by Eq. (15.135) is $c_2\left(C2sp^3HO\ to\ N\right)=0.91140$.

As given in the Continuous-Chain Alkanes ($C_nH_{2n+2},\ n=3,4,5...\infty$) section, each methylene group forms two single bonds, and the energy of each $C2sp^3$ HO of each CH_2 group alone is given by that in ethylene, $-1.13379\ eV$ (Eq. (14.511)). In secondary amines, the N of the NH group also binds to two $C2sp^3$ HOs and the corresponding $E_T\left(atom-atom,msp^3.AO\right)$ of each $C-N$ -bond MO in Eq. (15.61) due to the charge donation from the C and N atoms to the MO is $-1.13379\ eV$. It is based on the energy match between the N of the NH group to the two $C2sp^3$ HOs corresponding to the energy contributions to each of the two single bonds that are equivalent to those of independent methylene groups, $-1.13379\ eV$ (Eq. (14.511)), where the $N-H$ bond is also energy matched to the $C-N$ bonds. $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-N$ -bond MO in Eq. (15.61) due to the charge donation from the C and N atoms to the MO is $-1.13379\ eV$. It is based on the energy match between the N of the NH group to two $C2sp^3$ HOs corresponding to the energy contributions to the single bond that are equivalent to those of methyl groups, $-0.72457\ eV$ (Eq. (14.151)), where the $N-H$ bonds are also energy matched to the $C-N$ bond.

The symbols of the functional groups of branched-chain secondary amines are given in Table 15.75. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of secondary amines are given in Tables 15.76, 15.77, and 15.78, respectively. As in the case of NH_2 (Eq. (13.339)), $C_{1o}=2C_1$ rather than $C_{1o}=C_1$ in Eq. (15.61) for the $C-N$ bond. The total energy of each secondary amine given in Table 15.79 was calculated as the sum over the integer multiple of each $E_{D(Group)}$ of Table 15.78 corresponding to functional-group composition of the molecule. The bond angle parameters of secondary amines determined using Eqs. (15.88-15.117) are given in Table 15.80. The color scale, translucent view of the charge-density of exemplary secondary amine, dimenthylamine, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.13.

Figure 15.13. (A)-(B) Color scale, translucent views of the charge-density of dimethylamine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

TERTIARY AMINES ($C_nH_{2n+3}N,\ n=3,4,5...\infty$)

The tertiary amines, $C_nH_{2n+3}N$, have three $C-N$ bonds to methyl or alkyl groups wherein $C-N$ comprises a functional group. The alkyl portion of the tertiary amine may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in tertiary amines are equivalent to those in branched-chain alkanes.

The $C-N$ group is solved by hybridizing the $2s$ and $2p$ AOs of the C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the N AO to form a MO permits each participating orbital to decrease in radius and energy. In tertiary amines, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E(C,2sp^3)=-14.63489\ eV$ (Eq. (15.25)), and the N AO has an energy of $E(N)=-14.53414\ eV$. To meet the equipotential condition of the union of the $C-N$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.61) for the $C-N$-bond MO given by Eq. (15.135) is $c_2(C2sp^3 HO\ to\ \mathrm{N})=0.91140$.

As given in the Continuous-Chain Alkanes ($C_nH_{2n+2},\ n=3,4,5...\infty$) section, the energy of each $C2sp^3$ HO must be a linear combination of that of the CH_3 and CH_2 groups that serve as basis elements. Each CH_3 forms one $C-C$ bond, and each CH_2 group forms two. Thus, the energy of each $C2sp^3$ HO of each CH_3 and CH_2 group alone is given by that in ethane, $-0.72457\ eV$ (Eq. (14.151)), and ethylene, $-1.13379\ eV$ (Eq. (14.511)), respectively. In order to match the energy of the component HOs and MOs for the entire molecule, the energy $E_{T_{alkane}}(C-C,2sp^3)$ given as a linear combination of these basis elements is $-0.92918\ eV$ (Eq. (14.513)). In tertiary amines, the N binds to three $C2sp^3$ HOs and the corresponding $E_T(atom-atom,msp^3.AO)$ of each $C-N$-bond MO in Eq. (15.61) due to the charge donation from the C and N atoms to the MO is $-0.92918\ eV$. It comprises a linear combination of the energy for a primary amine, $-0.72457\ eV$ and a secondary amine, $-1.13379\ eV$.

The symbols of the functional groups of branched-chain tertiary amines are given in Table 15.81. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of tertiary amines are given in Tables 15.82, 15.83, and 15.84, respectively. The total energy of each tertiary amine given in Table 15.85 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.84 corresponding to functional-group composition of the molecule. The bond angle parameters of tertiary amines determined using Eqs. (15.88-15.117) are given in Table 15.86. The color scale, translucent view of the charge-density of exemplary tertiary amine, trimethylamine, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.14.

Figure 15.14. Color scale, translucent view of the charge-density of trimethylamine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (A) Top view. (B) Side view.

ALDEHYDES ($C_nH_{2n}O,\ n=1,2,3,4,5...\infty$)

The alkyl aldehydes, $C_nH_{2n}O$, each have a $HC=O$ moiety that comprises a $C=O$ functional group and a CH functional group. The single bond of carbon to the carbonyl carbon atom, $C-C(O)H$, is a functional group. In addition to the $C=O$ functional group, formaldehyde comprises a CH_2 functional group. The alkyl portion of the alkyl aldehyde may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in aldehydes are equivalent to those in branched-chain alkanes.

The CH functional group was solved in the Hydrogen Carbide (CH) section except that E_{mag} is not subtracted since unpaired electrons are not created with fragmentation of the CH functional group of aldehydes. The CH_2 functional group of formaldehyde is solved in the Dihydrogen Carbide (CH_2) section except that the energy of each $C-H$ MO is matched to the initial energy of the $C2sp^3$ HO (Eq. (15.25)). The $C=O$ and $C-C(O)H$ groups are solved by hybridizing the $2s$ and $2p$ AOs of each C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the O AO or between two $C2sp^3$ HOs, respectively, to form a MO permits each participating orbital to decrease in radius and energy. In alkyl aldehydes, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\,eV$ (Eq. (15.25)) and the O AO has an energy of $E(O)=-13.61806\,eV$. To meet the equipotential condition of the union of the $C=O$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.61) for the $C=O$-bond MO given by Eq. (15.133) is $c_2\left(C2sp^3HO\ to\ O\right)=0.85395$. The unpaired electrons created by bond breakage of the double $C=O$ bond requires that two times the $O2p$ AO magnetic energy E_{mag} (Eq. (15.69)) be subtracted from the total energy to give $E_{D(Group)}$ (eV) for $C=O$.

$E_T\left(atom-atom,msp^3.AO\right)$ of the $C=O$-bond MO in Eq. (15.61) due to the charge donation from the C and O atoms to the MO is $-2.69893\,eV$ which is an energy minimum for the double bond between the pair of $C2sp^3$ HO electrons of the C atom and the pair of AO electrons of the O atom. It is given as a linear combination of the energy contributions corresponding to a double bond, $-1.13379\,eV$ (Eq. (14.247)), and a triple bond, $-1.56513\,eV$ (Eq. (14.342)). The triple bond contribution includes the $C2sp^3$ HO electron of the $C-H$ bond in addition to the pair involved directly in the double bond with O. $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-C(O)H$ group is equivalent to that of an alkane, $-1.85836\,eV$, where both energy contributions are given by Eq. (14.513). It is based on the energy match between the $C2sp^3$ HOs of the aldehyde. In order to match energy between the groups bonded to the $C=O$, electron-density is shared. Due to the interaction in the transition state between the groups based on the sharing, $C_{1o}=2C_1$ rather than $C_{1o}=C_1$ in Eq. (15.61) for the $C-C(O)H$ bond.

The symbols of the functional groups of alkyl aldehydes are given in Table 15.87. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl aldehydes are given in Tables 15.88, 15.89, and 15.90, respectively. The total energy of each alkyl aldehyde given in Table 15.91 was calculated as the sum over the integer multiple of each $E_{D(Group)}$ of Table 15.90 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl aldehydes determined using Eqs. (15.88-15.117) are given in Table 15.92. The color scale, translucent view of the charge-density of exemplary aldehyde, Propanal, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.15.

Figure 15.15. (A)-(B) Color scale, translucent views of the charge-density of propanal showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

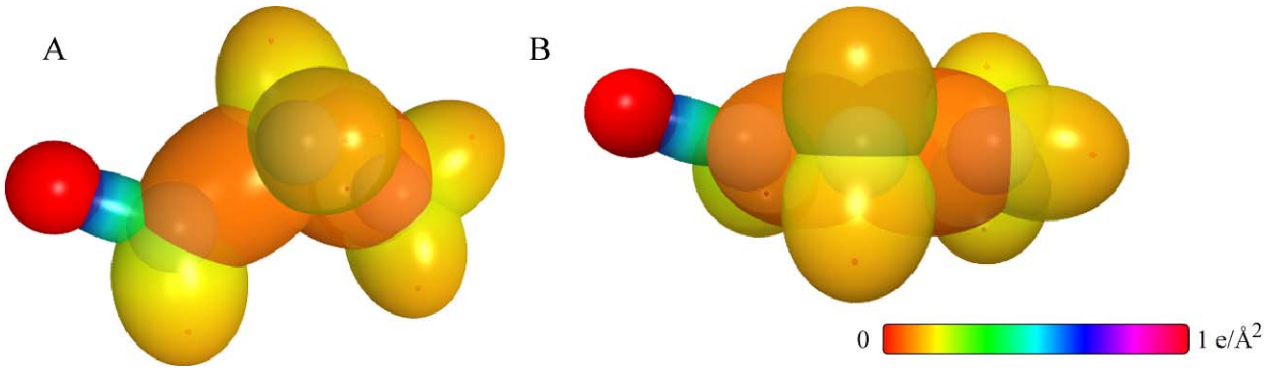

Table 15.87. The symbols of functional groups of alkyl aldehydes.

Functional Group	Group Symbol
CH_2 (formaldehyde) group	$C-H\ (CH_2)$ (i)
CH (aldehyde) group	CH (i)
C=O	$C=O$ (i)
C-C(O)H	$C-C(O)H$
CH_3 group	$C-H\ (CH_3)$
CH_2 (alkyl) group	$C-H\ (CH_2)$ (ii)
CH (alkyl)	$C-H$ (ii)
CC bond (*n-C)*	$C-C$ (a)
CC bond (*iso-C*)	$C-C$ (b)
CC bond (*tert-C*)	$C-C$ (c)
CC (*iso* to *iso-C*)	$C-C$ (d)
CC (*t* to *t-C*)	$C-C$ (e)
CC (*t* to *iso-C*)	$C-C$ (f)

KETONES ($C_nH_{2n}O,\ n=1,2,3,4,5...\infty$)

The alkyl ketones, $C_nH_{2n}O$, each have a $C=O$ moiety that comprises a functional group. Each of the two single bonds of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. The alkyl portion of the alkyl ketone may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in ketones are equivalent to those in branched-chain alkanes.

The $C=O$ and $C-C(O)$ groups are solved by hybridizing the $2s$ and $2p$ AOs of each C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the O AO or between two $C2sp^3$ HOs, respectively, to form a MO permits each participating orbital to decrease in radius and energy. In alkyl ketones, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)) and the O AO has an energy of $E(O)=-13.61806\ eV$. To meet the equipotential condition of the union of the $C=O$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.61) for the $C=O$-bond MO given by Eq. (15.133) is $c_2\left(C2sp^3HO\ to\ O\right)=0.85395$. The unpaired electrons created by bond breakage of the double $C=O$ bond requires that two times the $O2p$ AO magnetic energy E_{mag} (Eq. (15.69)) be subtracted from the total energy to give $E_{D\,(Group)}$ (eV) for $C=O$.

As in the case with aldehydes, $E_T\left(atom-atom,msp^3.AO\right)$ of the $C=O$-bond MO in Eq. (15.61) due to the charge donation from the C and O atoms to the MO is $-2.69893\ eV$ which is an energy minimum for the double bond between the pair of $C2sp^3$ HO electrons of the C atom and the pair of AO electrons of the O atom. It is given as a linear combination of the energy contributions corresponding to a double bond, $-1.13379\ eV$ (Eq. (14.247)), and a triple bond, $-1.56513\ eV$ (Eq. (14.342)). The triple bond contribution includes the $C2sp^3$ HO electron of the $C-C(O)$ bond in addition to the pair involved directly in the double bond with O. Consequently, $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-C(O)$-bond MO is $-1.44915\ eV$, corresponding to the energy contributions of the two $C2sp^3$ HOs to the single bond that are equivalent to those of methyl groups, $-0.72457\ eV$ (Eq. (14.151)). Since there are two $C-C(O)$ bonds in ketones versus one in aldehydes, $C_{1o}=C_1$ in Eq. (15.61) for each $C-C(O)$ ketone bond.

The symbols of the functional groups of alkyl ketones are given in Table 15.93. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.64)) parameters of alkyl ketones are given in Tables 15.94, 15.95, and 15.96, respectively. The total energy of each alkyl ketone given in Table 15.97 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.96 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage , the $C2sp^3$ HO magnetic energy E_{mag} that is subtracted from the weighted sum of the $E_{D\,(Group)}$ (eV) values based on composition is given by Eq. (15.67). The bond angle parameters of alkyl ketones determined using Eqs. (15.88-15.117) are given in Table 15.98. The color scale, translucent view of the charge-density of exemplary ketone, methyl ethyl ketone, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.16.

Figure 15.16. (A)-(B) Color scale, translucent views of the charge-density of methyl ethyl ketone showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

CARBOXYLIC ACIDS ($C_nH_{2n}O_2,\ n=1,2,3,4,5...\infty$)

The alkyl carboxylic acids, $C_nH_{2n}O_2$, comprise a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. Formic acid has a $HC=O$ moiety that comprises a more stable $C=O$ functional group and a CH functional group. All carboxylic acids further comprise a $C-OH$ moiety that comprises $C-O$ and OH functional groups. The alkyl portion of the alkyl carboxylic acid may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in carboxylic acids are equivalent to those in branched-chain alkanes.

The CH functional group was solved in the Hydrogen Carbide (CH) section except that the energy of the $C-H$ MO is matched to the carbon-atom contribution to $\Delta E_{H_2MO}(AO/HO)$ and $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-O$ group. The alkyl carboxylic acid $C=O$ and $C-C(O)$ groups are equivalent to those given in the Aldehydes section except that $\overline{E}_{Kvib}$ is that of a carboxylic acid, and $C-C(O)$ is equivalent to the n-alkane $C-C$ bond group in the case of conjugated carbonyls wherein the alkene groups when present such as the $C=C$ group are equivalent to those of the corresponding alkene. The formic acid $C=O$ group is solved equivalently to that of the alkyl carboxylic acid group, except that $\Delta E_{H_2MO}(AO/HO)$ and $E_T\left(atom-atom,msp^3.AO\right)$ correspond to a 25% increase in the donation of charge density from the orbitals of the atoms to the $C=O$ MO due to the presence of a H bound to the carbonyl carbon. Also, $\overline{E}_{Kvib}$ is that corresponding to formic acid. The $C-O$ and OH groups are equivalent to those of alkyl alcohols given in the corresponding section except that the energy of the $C-O$ MO is matched to that of the $C=O$ group and $\overline{E}_{Kvib}$ is that of a carboxylic acid. $\Delta E_{H_2MO}(AO/HO)$ of the $C-O$ group is equal to $E_T\left(atom-atom,msp^3.AO\right)$ of the alkyl $C=O$ group in order to match the energies of the corresponding MOs.

As in the case with aldehydes and ketones, $E_T\left(atom-atom,msp^3.AO\right)$ of the $C=O$-bond MO in Eq. (15.61) of alkyl carboxylic acids due to the charge donation from the C and O atoms to the MO is $-2.69893\ eV$ which is an energy minimum for the double bond between the pair of $C2sp^3$ HO electrons of the C atom and the pair of AO electrons of the carbonyl O atom. It is given as a linear combination of the energy contributions corresponding to a double bond, $-1.13379\ eV$ (Eq. (14.247)), and a triple bond, $-1.56513\ eV$ (Eq. (14.342)). The triple bond contribution includes the energy match of the carbonyl $C2sp^3$ HO electron with the O of the $C-O$-bond MO in addition to the pair involved directly in the double bond with the carbonyl O.

$E_T\left(atom-atom,msp^3.AO\right)$ of the formic acid $C=O$-bond MO in Eq. (15.61) due to the charge donation from the C and O atoms to the MO is $-3.58557\ eV$. This is also an energy minimum for the double bond between the pair of $C2sp^3$ HO electrons of the C atom and the pair of AO electrons of the carbonyl O atom. It is given as a linear combination of the energy contributions corresponding to a triple bond, $-1.56513\ eV$ (Eq. (14.342)), and a quadruple bond, $-2.02043\ eV$ (Eqs. (15.18-15.21) with $s=4$)) where the bond order components are increased by an integer over that of alkyl carboxylic acids due to the presence of a H bound to the carbonyl carbon.

$E_T\left(atom-atom,msp^3.AO\right)$ of the carboxylic acid $C-C(O)$ group is equivalent to that of alkanes and aldehydes, $-1.85836\ eV$, where both energy contributions are given by Eq. (14.513). It is based on the energy match between the $C2sp^3$ HOs of the carboxylic acid. As in the case of aldehydes, $C_{1o}=2C_1$ in Eq. (15.52).

$E_T\left(atom-atom,msp^3.AO\right)$ of the carboxylic acid $C-O$ group is equivalent to that of alkyl alcohols, $-1.85836\ eV$. It is based on the energy match between the O AO and the $C2sp^3$ HO of a methylene group (the maximum hybridization for a single bond) where both energy contributions are given by Eq. (14.513). $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-O$ group matches that of the $C-C(O)$ group.

The symbols of the functional groups of alkyl carboxylic acids are given in Table 15.99. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl carboxylic acids are given in Tables 15.100, 15.101, and 15.102, respectively. The total energy of each alkyl carboxylic acid given in Table 15.103 was calculated as the sum over the integer multiple of each $E_{D(Group)}$ of Table 15.102 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C2sp^3$ HO magnetic energy E_{mag} that is subtracted from the weighted sum of the $E_{D(Group)}$ (eV) values based on composition is given by Eq. (15.67). The bond angle parameters of alkyl carboxylic acids determined using Eqs. (15.79-15.108) are given in Table

15.104. The color scale, translucent view of the charge-density of exemplary carboxylic acid, Propanoic acid, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.17.

Figure 15.17. (A)-(B) Color scale, translucent views of the charge-density of propanoic acid showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.103. The total bond energies of alkyl carboxylic acids calculated using the functional group composition and the energies of Table 15.102 compared to the experimental values [3]. The magnetic energy E_{mag} that is subtracted from the weighted sum of the E_D $(_{Group})$ (eV) values based on composition is given by (15.57).

CARBOXYLIC ACID ESTERS ($C_nH_{2n}O_2,\ n=1,2,3,4,5...\infty$)

The alkyl carboxylic acid esters, $C_nH_{2n}O_2$, comprise a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. Formic acid ester has a $HC=O$ moiety that comprises a more stable $C=O$ functional group and a CH functional group. All carboxylic acid esters further comprise a COR moiety that comprises a $C-O$ functional group and three types of $O-R$ functional groups, one for R comprising methyl, one for R comprising an alkyl ester group of a formate, and one for R comprising an alkyl ester group of an alkyl carboxylate. The alkyl portion of the alkyl carboxylic acid ester may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in carboxylic acid esters are equivalent to those in branched-chain alkanes.

The CH functional group is equivalent to that of formic acid. The alkyl carboxylic acid ester $C=O$ and $C-C(O)$ groups are equivalent to those given in the Carboxylic Acids section. The formic acid ester $C=O$ group is equivalent to that given in the Carboxylic Acids section except that $\overline{E}_{Kvib}$ is that corresponding to a formic acid ester. The $C-O$ group is equivalent to that given in the Carboxylic Acids section except that the parameters corresponding to oscillation of the bond in the transition state, $\overline{E}_D\ (eV)$ and $\overline{E}_{Kvib}$, are those of a carboxylic acid ester. As in the case with the alkyl ethers, each $O-C$ group is solved by hybridizing the $2s$ and $2p$ AOs of the C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the O AO to form a MO permits each participating orbital to decrease in radius and energy. To meet the equipotential condition of the union of the $O-C$ H_2-type-ellipsoidal-MO with other orbitals of the molecule, the hybridization factor c_2 of Eq. (15.60) for the $O-C$-bond MO given by Eq. (15.133) is: $c_2\left(C2sp^3 HO\ to\ O\right)=0.85395$.

$E_T\left(atom-atom, msp^3.AO\right)$ (Eq. (15.61)) of (1) the $C=O$ group of alkyl carboxylic acid esters, (2) the $C=O$ group of formic acid esters, (3) the alkyl carboxylic acid ester $C-C(O)$ group, and (4) the carboxylic acid ester $C-O$ group are equivalent to those of the corresponding carboxylic acids. The values given in the Carboxylic Acids section are $-2.69893\ eV$, $-3.58557\ eV$, $-1.85836\ eV$, and $-1.85836\ eV$, respectively. $E_T\left(atom-atom, msp^3.AO\right)$ of the $C-O$ group matches that of the $C-C(O)$ group. Also, as in the case of aldehydes, $C_{1o}=2C_1$ in Eq. (15.61) for the $C-C(O)$ group.

$E_T\left(atom-atom, msp^3.AO\right)$ of the $O-C$-bond MO in Eq. (15.61) due to the charge donation from the C and O atoms to the MO is $-1.13379\ eV$ for the $O-CH_3$ group of formate and alkyl carboxylates, $-1.44915\ eV$ for the $O-R$ group of alkyl carboxylates, and $-1.85836\ eV$ for the $O-R$ group of alkyl formates, where R is an alkyl group. Each is based on the energy match between the O AO, initially at the Coulomb potential of a proton and an electron (Eqs. (1.257) and (10.162), respectively), the $C2sp^3$ HO of the methyl or alkyl ester group, and the carbonyl carbon. The increasing energy contributions to the single bond correspond to the increasing hybridization of linear combinations of increasing bond order. The energy contributions corresponding to one half of a double bond and those of the methyl-methyl and methylene-methylene bonds are $-1.13379\ eV$ (Eq. (14.247)), two times $-0.72457\ eV$ (Eq. (14.151)), and two times $-0.92918\ eV$ (Eq. (14.513)), respectively.

The symbols of the functional groups of alkyl carboxylic acid esters are given in Table 15.105. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl carboxylic acid esters are given in Tables 15.106, 15.107, and 15.108, respectively. The total energy of each alkyl carboxylic acid ester given in Table 15.109 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.108 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage , the $C2sp^3$ HO magnetic energy E_{mag} that is subtracted from the weighted sum of the $E_{D\,(Group)}\ (eV)$ values based on composition is given by Eq. (15.67). The bond angle parameters of alkyl carboxylic acid esters determined using Eqs. (15.88-15.117) are given in Table 15.110. The color scale, translucent view of the charge-density of exemplary carboxylic acid ester, methyl acetate, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.18.

Figure 15.18. Color scale, translucent view of the charge-density of methyl acetate showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

Table 15.109. The total bond energies of alkyl carboxylic acid esters calculated using the functional group composition and the energies of Table 15.108 compared to the experimental values [3]. The magnetic energy E_{mag} that is subtracted from the weighted sum of the E_D $(Group)$ (eV) values based on composition is given by (15.57).

AMIDES ($C_nH_{2n+1}NO,\ n=1,2,3,4,5...\infty$)

The alkyl amides, $C_nH_{2n+1}NO$, comprise a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. Formamide has a $HC=O$ moiety that comprises a more stable $C=O$ functional group and a CH functional group that is equivalent to that of the CH (i) of aldehydes given in the corresponding section. It is also equivalent to that of the iso-CH group of branched-chain-alkyl portion of the alkyl amide except that E_{mag} (Eq. (15.47)) is not subtracted from $E_D(Group)$. All amides further comprise a $C-NH_2$ moiety that comprises a NH_2 functional group and two types of $C-N$ functional groups, one for formamide and the other for alkyl amides ($RC(O)NH_2$ where R is alkyl). The alkyl portion of the alkyl amide may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in amides are equivalent to those in branched-chain alkanes.

The NH_2 functional group was solved in the Dihydrogen Nitride (NH_2) section except that the energy of the $N-H$ MO is matched to the nitrogen-atom contribution to $\Delta E_{H_2MO}(AO/HO)$ and $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-N$ group. Both alkyl amide $C=O$ groups and the $C-C(O)$ group are equivalent to those given in the Carboxylic Acid Esters section except that $\bar{E}_{Kvib}$ of the $C-C(O)$ group is matched to that of an amide. The $C-N$ groups are equivalent to those of alkyl amines given in the corresponding section except that the energy of the $C-N$ MO is matched to that of the $C=O$ group and $\bar{E}_{Kvib}$ is that of a amide. $\Delta E_{H_2MO}(AO/HO)$ of the $C-N$ group is equal to $E_T\left(atom-atom,msp^3.AO\right)$ of the alkyl $C=O$ and $C-N$ groups in order to match the energies of the corresponding MOs.

As in the case of primary amines, each $C-N$ group is solved by hybridizing the $2s$ and $2p$ AOs of the C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the N AO to form a MO permits each participating orbital to decrease in radius and energy. To meet the equipotential condition of the union of the $C-N$ H_2-type-ellipsoidal-MO with other orbitals of the molecule, the hybridization factor c_2 of Eq. (15.52) for the $C-N$-bond MO given by Eq. (15.133) is $c_2\left(C2sp^3HO\ to\ N\right)=0.91140$.

$E_T\left(atom-atom,msp^3.AO\right)$ (Eq. (15.52)) of the $C=O$ group of alkyl amides and the $C=O$ group of formamide are equivalent to those of the corresponding carboxylic acids and esters. The values given in the Carboxylic Acids section are $-2.69893\ eV$ and $-3.58557\ eV$, respectively.

$E_T\left(atom-atom,msp^3.AO\right)$ of the amide $C-C(O)$ group is the same as alkanes, aldehydes, carboxylic acids, and carboxylic acid esters, $-1.85836\ eV$, where both energy contributions are given by Eq. (14.513). Also, as in the case of aldehydes, $C_{1o}=2C_1$ in Eq. (15.61).

In order to match energy throughout the chain of the amide molecule, $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-N$-bond MO in Eq. (15.61) due to the charge donation from the C and N atoms to the MO is $-1.65376\ eV$. It is based on the energy match between the $C2sp^3$ HO of the carbonyl and the primary amino group NH_2. It is given by the linear combination of $-0.92918\ eV$ (Eq. (14.513)) which matches the contiguous $C-C(O)$ or $HC(O)$ group and $-0.72457\ eV$ (Eq. (14.151)), the contribution of a primary amino group given in the Primary Amines section.

The symbols of the functional groups of alkyl amides are given in Table 15.111. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl amides are given in Tables 15.112, 15.113, and 15.114, respectively. The total energy of each alkyl amide given in Table 15.115 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.114 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl amides determined using Eqs. (15.88-15.117) are given in Table 15.116. The color scale, translucent view of the charge-density of exemplary amide, propionamide, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.19.

Figure 15.19. (A)-(B) Color scale, translucent views of the charge-density of propionamide showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

N-ALKYL AND N,N-DIALKYL-AMIDES ($C_nH_{2n+1}NO,\ n=2,3,4,5...\infty$)

The N-alkyl and N,N-dialkyl amides, $C_nH_{2n+1}NO$, comprise a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. Formamide has a $HC=O$ moiety that comprises a more stable $C=O$ functional group and a CH functional group that is equivalent to that of the iso-CH group of branched-chain-alkyl portion of the N-alkyl or N,N-dialkyl amide. All amides further comprise a $C-N\left(R_1\right)R_2$ moiety that comprises two types of $C-N$ functional groups, one for formamide and the other for alkyl amides ($RC(O)N\left(R_1\right)R_2$ where R is alkyl). The N or N,N-dialkyl moiety comprises three additional groups depending on the alkyl substitution of the nitrogen. In the case of a single methyl or alkyl substitution, the $NH-C$ bond and NH are functional groups, and the $N-C$ bond of a di-substituted nitrogen is the third.

The alkyl portion of the N-alkyl or N,N-dialkyl amide may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($\left(CH_3\right)_2CH$) and t-butyl ($\left(CH_3\right)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in N-alkyl or N,N-dialkyl amides are equivalent to those in branched-chain alkanes.

The NH functional group was solved in the Hydrogen Nitride (NH) section except that the energy of the $N-H$ MO is matched to the nitrogen-atom contribution to $\Delta E_{H_2MO}\left(AO/HO\right)$ and $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-N$ group. The $C-C(O)$ group, both N-alkyl or N,N-dialkyl amide $C=O$ groups, and both $C-N$ groups are equivalent to those given in the Amides section.

As in the case of primary amines, each $N-C$ group is solved by hybridizing the $2s$ and $2p$ AOs of the C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the N AO to form a MO permits each participating orbital to decrease in radius and energy. To meet the equipotential condition of the union of the $N-C$ H_2-type-ellipsoidal-MO with other orbitals of the molecule, the hybridization factor c_2 of Eq. (15.61) for the $N-C$-bond MO given by Eq. (15.133) is $c_2\left(C2sp^3HO\ to\ N\right)=0.91140$.

$E_T\left(atom-atom,msp^3.AO\right)$ of the N-substituted amide $C-C(O)$ group is the same as alkanes, aldehydes, carboxylic acids, carboxylic acid esters, and amides, $-1.85836\ eV$, where both energy contributions are given by Eq. (14.513). Also, as in the case of aldehydes, $C_{1o}=2C_1$ in Eq. (15.61).

$E_T\left(atom-atom,msp^3.AO\right)$ (Eq. (15.61)) of the $C=O$ group of N-substituted alkyl amides and the $C=O$ group of N-substituted formamide are equivalent to those of the corresponding carboxylic acids, carboxylic esters, and amides. The values given in the Carboxylic Acids section are $-2.69893\ eV$ and $-3.58557\ eV$, respectively.

$E_T\left(atom-atom,msp^3.AO\right)$ of both $C-N$ functional groups are the same as those of the corresponding groups of amides, $-1.65376\ eV$. $E_T\left(atom-atom,msp^3.AO\right)$ of the singly-substituted $NH-C$-bond MO in Eq. (15.61) due to the charge donation from the N and C atoms to the MO is $-0.92918\ eV$. It is equivalent to that of tertiary amines and matches the energy of the $NH-C$ group to that of the $C-N$ group wherein $E_T\left(atom-atom,msp^3.AO\right)$ of the latter is a linear combination of $-0.92918\ eV$ (Eq. (14.513)) and $-0.72457\ eV$ (Eq. (14.151)). $E_T\left(atom-atom,msp^3.AO\right)$ of the doubly-substituted $N-C$-bond MO is $-0.72457\ eV$. It is equivalent to that of the contribution of each atom of a primary amine and also matches the energy of the $N-C$ group to that of the $C-N$ group by matching one of the components of $E_T\left(atom-atom,msp^3.AO\right)$ of the latter.

The symbols of the functional groups of N-alkyl and N,N-dialkyl amides are given in Table 15.117. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of N-alkyl and N,N-dialkyl amides are given in Tables 15.118, 15.119, and 15.120, respectively. The total energy of each N-alkyl or N,N-dialkyl amide given in Table 15.121 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.120 corresponding to functional-group composition of the molecule. The bond angle parameters of N-alkyl and N,N-dialkyl amides determined using Eqs. (15.79-15.108) are given in Table 15.122. The color scale, translucent view of the charge-density of exemplary alkyl-amide, N,N-dimethylacetamide, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.20.

Figure 15.20. Color scale, translucent view of the charge-density of N,N-dimethylacetamide showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

UREA (CH_4N_2O)

Urea, CH_4N_2O, comprises a $C=O$ functional group and two $C-NH_2$ moieties that each comprise a NH_2 functional group and a $C-N$ functional group. The $C=O$ group is equivalent to that given for formamide in the Amides section except that the energy terms due to oscillation in the transition state are matched to that of urea. The NH_2 and $C-N$ functional groups are also equivalent to those given in the Amides section. $E_T\left(atom-atom,msp^3.AO\right)$ (Eq. (15.61)) of the $C=O$ and $C-N$ groups are equivalent to those of formamide. The values given in the Amides section are $-3.58557\,eV$, and $-1.65376\,eV$, respectively.

The symbols of the functional groups of urea are given in Table 15.123. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of urea are given in Tables 15.124, 15.125, and 15.126, respectively. The total energy of urea given in Table 15.127 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.126 corresponding to functional-group composition of the molecule. The bond angle parameters of urea determined using Eqs. (15.88-15.117) are given in Table 15.128. The color scale, translucent view of the charge-density of urea comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.21.

Figure 15.21. Color scale, translucent view of the charge-density of urea showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

CARBOXYLIC ACID HALIDES ($C_nH_{2n-1}OX,\ X=F,Cl,Br,I;\ n=1,2,3,4,5...\infty$)

The alkyl carboxylic acid halides, $C_nH_{2n-1}OX$, comprise a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. All carboxylic acid halides further comprise a $C-X$ functional group where X is a halogen atom. The alkyl portion of the alkyl carboxylic acid halide may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in carboxylic acids are equivalent to those in branched-chain alkanes.

The alkyl carboxylic acid halide $C=O$ and $C-C(O)$ groups are equivalent to those given in the Aldehydes section and the Ketones section, respectively. The values of $E_T\left(atom-atom,msp^3.AO\right)$ given in these sections are $-2.69893\ eV$ and $-1.44915\ eV$, respectively.

As in the case of alkyl halides, each $(O)C-X$ group is solved by hybridizing the $2s$ and $2p$ AOs of the C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the X AO to form a MO permits each participating orbital to decrease in radius and energy. For example, to meet the equipotential condition of the union of the $(O)C-Cl$ H_2-type-ellipsoidal-MO with other orbitals of the molecule, the hybridization factor C_2 of Eq. (15.61) for the $(O)C-Cl$-bond MO given by Eq. (15.130) is $C_2\left(C2sp^3HO\ to\ Cl\right)=0.81317$. The solution is equivalent to that of the alkyl chloride bond except that the energy parameters corresponding to oscillation in the transition state are matched to those of a carboxylic acid chloride.

As in the case with the $C-Cl$ group of alkyl chlorides, $E_T\left(atom-atom,msp^3.AO\right)$ of the $(O)C-Cl$-bond MO in Eq. (15.61) of alkyl carboxylic acid chlorides due to the charge donation from the C and Cl atoms to the MO is $-1.44915\ eV$ where both energy contributions are given by Eq. (14.511). This matches the energy of the $C-C(O)$ functional group with that of the $(O)C-Cl$ group within the carboxylic acid chloride molecule.

The symbols of the functional groups of alkyl carboxylic acid chlorides are given in Table 15.129. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl carboxylic acid chlorides are given in Tables 15.130, 15.131, and 15.132, respectively. The total energy of each alkyl carboxylic acid chloride given in Table 15.133 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.132 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl carboxylic acid chlorides determined using Eqs. (15.88-15.117) are given in Table 15.134. The color scale, translucent view of the charge-density of exemplary carboxylic acid halide, acetyl chloride, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.22.

Figure 15.22. Color scale, translucent view of the charge-density of acetyl chloride showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

CARBOXYLIC ACID ANHYDRIDES ($C_nH_{2n-2}O_3,\ n=2,3,4,5...\infty$)

The alkyl carboxylic acid anhydrides, $C_nH_{2n-2}O_3$, have two $(O)C-O$ moieties that each comprise $C=O$ and $C-O$ functional groups. The single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. The alkyl portion of the alkyl carboxylic acid anhydride may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in carboxylic acid anhydrides are equivalent to those in branched-chain alkanes.

The alkyl carboxylic acid anhydride $C=O$ and $C-C(O)$ groups are equivalent to those given in the Carboxylic Acid Esters section and the Ketones section, respectively. The values of $E_T\left(atom-atom,msp^3.AO\right)$ given in these sections are $-2.69893\ eV$ and $-1.44915\ eV$, respectively. The $C-O$ group is also equivalent to that given in the Carboxylic Acid Esters section except that $E_T\left(atom-atom,msp^3.AO\right)$ is equivalent to that of an alkyl ether as given in the corresponding section and the energy terms due to oscillation in the transition state are matched to that of a carboxylic acid anhydride.

For the $C-O$ group, $E_T\left(atom-atom,msp^3.AO\right)$ is $-1.65376\ eV$. It is based on the energy match between the O AO and the $C2sp^3$ HO of each $C-C(O)$ group and is given by the linear combination of $-0.72457\ eV$ (Eq. (14.151)) and $-0.92918\ eV$ (Eq. (14.513)), respectively. This matches $-0.72457\ eV$, the energy contribution of each of the $C2sp^3$ HOs to each $C-C(O)$ functional group, with that of the corresponding energy component of the $C-O$ group and gives a minimum energy within the carboxylic acid anhydride molecule.

The symbols of the functional groups of alkyl carboxylic acid anhydrides are given in Table 15.135. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl carboxylic acid anhydrides are given in Tables 15.136, 15.137, and 15.138, respectively. The total energy of each alkyl carboxylic acid anhydride given in Table 15.139 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.138 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl carboxylic acid anhydrides determined using Eqs. (15.88-15.117) are given in Table 15.140. The color scale, translucent view of the charge-density of exemplary carboxylic acid anhydride, acetic anhydride, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.23.

Figure 15.23. (A)-(B), color scale, translucent views of the charge-density of acetic anhydride showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

NITRILES ($C_nH_{2n-1}N,\ n=2,3,4,5...\infty$)

The nitriles, $C_nH_{2n-1}N$, comprise a $C\equiv N$ functional group, and the single bond of carbon to the nitrile carbon atom, $C-CN$, is also a functional group. The alkyl portion of the nitrile may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in nitriles are equivalent to those in branched-chain alkanes.

The nitrile $C\equiv N$ is solved equivalently to acetylene as given in the Acetylene Molecule section except that the energy for $E_{(AO/HO)}$ is two times that given in Eq. (14.343), 16.20002 eV, in order to match the N AOs to that of the nitrile $C2sp^3$ HO having a bond order of three. $E_T\left(atom-atom,msp^3.AO\right)$ of the $C\equiv N$ functional group is $-1.56513\,eV$ (Eq. (14.342)) corresponding to the third-order bonded $C2sp^3$ HO.

The $C-CN$ functional group is equivalent to that of an alkyl $C-C$ group given in the Continuous-Chain Alkanes section except that $E_{T(H_2MO)}$ and $\bar{E}_{Kvib}$ are those corresponding to a nitrile. As given in the Continuous-Chain Alkanes section, $E_T\left(atom-atom,msp^3.AO\right)$ of the alkyl $C-C$ group is $-1.85836\,eV$ where both energy contributions are given by Eq. (14.513). It is based on energy matching within the nitrile. It corresponds to the maximum-magnitude energy contributions of a single-bonded and a third-order bonded $C2sp^3$ HO.

The symbols of the functional groups of nitriles are given in Table 15.141. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of nitriles are given in Tables 15.142, 15.143, and 15.144, respectively. The total energy of each nitrile given in Table 15.139 was calculated as the sum over the integer multiple of each $E_{D(Group)}$ of Table 15.144 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C2sp^3$ HO magnetic energy E_{mag} that is subtracted from the weighted sum of the $E_{D(Group)}$ (eV) values based on composition is given by Eq. (15.67). The bond angle parameters of nitriles determined using Eqs. (15.88-15.117) are given in Table 15.146. The C of the $C\equiv N$ group can further bond with only one atom, and the bond is linear as a minimum of energy as in the case of acetylene and alkynes. The color scale, translucent view of the charge-density of exemplary nitrile, propanenitrile, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.24.

Figure 15.24. Color scale, translucent view of the charge-density of propanenitrile showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

THIOLS ($C_nH_{2n+2}S_m,\ n=1,2,3,4,5...\infty$)

The alkyl thiols, $C_nH_{2n+2}S_m$, comprise a SH functional group and a $C-S$ functional group. The alkyl portion of the alkyl thiol may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in thiols are equivalent to those in branched-chain alkanes.

The parameters of the SH functional group is solved using Eq. (15.41). As in the case of the $C-H$ bonds of CH_n $n=1,2,3$, the $S-H$-bond MO is a partial prolate spheroid in between the sulfur and hydrogen nuclei and is continuous with the $S3p$ shell. The energy of the H_2-type ellipsoidal MO is matched to that of the $S3p$ shell and comprises 75% of a H_2-type ellipsoidal MO in order to match potential, kinetic, and orbital energy relationships. Since the energy of S, $E(S)=-10.36001\ eV$, is less that that of H, the linear combination of the H_2-type ellipsoidal MO with the $S3p$ shell further comprises an excess 50% charge-density donation from H to the $S3p$ shell of the $S-H$-bond MO to achieve an energy minimum. The initial total energy of the shell is given by the sum over the four $3p$ electrons. From Eq. (15.12), the sum $E_T(S,3p)$ of the energies of S, S^+, S^{2+}, and S^{3+} [38] is:

$$E_T(S,3p)=10.36001\ eV+23.33788\ eV+34.79\ eV+47.222\ eV=115.70989\ eV \tag{15.137}$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius r_{3p} of the $S3p$ shell may be calculated from the Coulombic energy using Eqs. (15.13) and (15.137).

$$r_{3p}=\sum_{q=12}^{15}\frac{(Z-q)e^2}{8\pi\varepsilon_0\left(e115.70989\ eV\right)}=\frac{10e^2}{8\pi\varepsilon_0\left(e115.70989\ eV\right)}=1.17585a_0 \tag{15.138}$$

where $Z=16$ for sulfur. Using Eqs. (15.14) and (15.138), the Coulombic energy $E_{Coulomb}(S,3p)$ of the outer electron of the $S3p$ shell is:

$$E_{Coulomb}(S,3p)=\frac{-e^2}{8\pi\varepsilon_0 r_{3p}}=\frac{-e^2}{8\pi\varepsilon_0 1.17585a_0}=-11.57099\ eV \tag{15.139}$$

The sharing of the electrons between the S and H atoms permits the formation an $S-H$-bond MO that is lowered more in energy than the participating $S3p$ orbital which consequently increases in energy. By considering the 50% electron redistribution in the $S-H$ group as well as the fact that the central field decreases by an integer for each successive electron of the shell, the radius r_{S-H3p} of the $S3p$ shell may be calculated from the Coulombic energy using Eq. (15.18).

$$r_{S-H3p}=\left(\sum_{n=12}^{15}(Z-n)+2(0.25)\right)\frac{e^2}{8\pi\varepsilon_0\left(e115.70989\ eV\right)}=\frac{10.5e^2}{8\pi\varepsilon_0\left(e115.70989\ eV\right)}=1.23465a_0 \tag{15.140}$$

where the $s=-2$ in Eq. (15.18) due to the charge donation from H to S. Using Eqs. (15.19) and (15.121), the Coulombic energy $E_{Coulomb}(S_{S-H},3p)$ of the outer electron of the $S3p$ shell is:

$$E_{Coulomb}(S_{S-H},3p)=\frac{-e^2}{8\pi\varepsilon_0 r_{S-H3p}}=\frac{-e^2}{8\pi\varepsilon_0 1.23465a_0}=-11.01999\ eV \tag{15.141}$$

Thus, $E_T(S-H,3p)$, the energy change of each $S3p$ shell with the formation of the $S-H$-bond MO is given by the difference between Eq. (15.139) and Eq. (15.141):

$$E_T(S-H,3p)=E(S_{S-H},3p)-E(S,3p)=-11.01999\ eV-(-11.57099\ eV)=0.55100\ eV \tag{15.142}$$

Then, in Eq. (15.51):

$$E_T(AO/HO)=E(S)-E_T(S-H,3p)=-10.36001\ eV-0.55100\ eV=-10.91101\ eV \tag{15.143}$$

And, in Eq. (15.65),

$$E_T(atom-atom,msp^3.AO)=0.55100\ eV \tag{15.144}$$

Due to the charge donation from H to S, $c_1 = 1$ in both Eqs. (15.51) and (15.65). As in the case of the $C-H$-bond MO, $C_1 = 0.75$ based on the orbital composition. In alkyl thiols, the energy of sulfur is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264). Thus, c_2 in Eq. (15.61) is also one, and the energy matching condition is determined by the C_2 parameter. Using the energy of S, $E(S) = -10.36001\ eV$ in Eq. (15.74), the hybridization factor C_2 of Eq. (15.61) for the $S-H$-bond MO is:

$$C_2(S3p\ to\ H) = \frac{E(S,3p)}{E(H)} = \frac{-10.36001\ eV}{-13.60580\ eV} = 0.76144 \tag{15.145}$$

Since the energy of S is matched to the Coulombic energy between the electron and proton of H, $E(H(a_0))$, $E_{initial}(c_4 AO/HO) = E(H(a_0)) = -13.60580\ eV$, $E_{initial}(c_5 AO/HO) = E(H) = -13.59844\ eV$, and E_{mag} is that corresponding to $E(H(a_0))$ given by Eq. (15.67). $E_D(Group)$ for hydrogen sulfide is equivalent to that of the SH functional group, and the $E_D(Group)$ (eV) for dihydrogen sulfide follows the same derivation as that for the SH functional group except that the parameters correspond to $n_1 = 2$ rather than $n_1 = 1$ in Eqs. (15.51) and (15.65).

Furthermore, with the energy of S matched to the Coulombic energy between the electron and proton of H, the energy of the $C-S$-bond MO is the sum of the component energies of the H_2-type ellipsoidal MO given in Eq. (15.51) with $E(AO/HO) = 0$ and $E_T(AO/HO) = \Delta E_{H_2 MO}(AO/HO)$. Then, the solution of the $C-S$ functional group comprises the hybridization of the $2s$ and $2p$ AOs of C to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the S AO to form a MO permits each participating orbital to decrease in radius and energy. Since the energy of sulfur is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264), c_2 in Eq. (15.61) is one, and the energy matching condition is determined by the C_2 parameter. Then, $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E(C,2sp^3) = -14.63489\ eV$ (Eq. (15.25)), and the S AO has an energy of $E(S) = -10.36001\ eV$. To meet the equipotential condition of the union of the $C-S$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor C_2 of Eq. (15.60) for the $C-S$-bond MO given by Eqs. (15.77) and (15.79) is:

$$C_2(C2sp^3 HO\ to\ \mathrm{S}) = \frac{E(S)}{E(C,2sp^3)} c_2(C2sp^3 HO) = \frac{-10.36001\ eV}{-14.63489\ eV}(0.91771) = 0.64965 \tag{15.146}$$

Since the sulfur is energy matched to $E(H(a_0))$ in the $S-H$-bond MO, $E_T(atom-atom, msp^3.AO)$ of the $C-S$-bond MO in Eq. (15.61) due to the charge donation from the C and S atoms to the MO is $-0.72457\ eV$ corresponding to the energy contribution equivalent to that of a methyl group (Eq. (14.151)).

The symbols of the functional groups of branched-chain alkyl thiols are given in Table 15.147. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl thiols are given in Tables 15.148, 15.149, and 15.150, respectively. The total energy of each alkyl thiol given in Table 15.151 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.150 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C2sp^3$ HO magnetic energy E_{mag} that is subtracted from the weighted sum of the $E_D(Group)$ (eV) values based on composition is given by Eq. (15.67). The $C-C$ bonds to the $HCSH$ group (one H bond to C) were each treated as an iso $C-C$ bond. The $C-C$ bonds to the CSH group (no H bonds to C) were each treated as a tert-butyl $C-C$. E_{mag} was subtracted for each t-butyl group. The bond angle parameters of alkyl thiols determined using Eqs. (15.88-15.117) are given in Table 15.152. The color scale, translucent view of the charge-density of exemplary thiol, ethanethiol, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.25.

Figure 15.25. Color scale, translucent view of the charge-density of ethanethiol showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

SULFIDES ($C_nH_{2n+2}S_m,\ n=2,3,4,5...\infty$)

The alkyl sulfides, $C_nH_{2n+2}S_m$, comprise two types of $C-S$ functional groups, one for t-butyl groups corresponding to the C and the other for the remaining general alkyl groups including methyl. The alkyl portion of the alkyl sulfide may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in sulfides are equivalent to those in branched-chain alkanes.

Each $C-S$ group is solved by hybridizing the $2s$ and $2p$ AOs of the C atom to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the S AO to form a MO permits each participating orbital to decrease in radius and energy. Since the energy of sulfur is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264), c_2 in Eq. (15.61) is one, and the energy matching condition is determined by the C_2 parameter. As in the case of thiols, C_2 of Eq. (15.61) for the $C-S$-bond MO given by Eq. (15.146) is $C_2\left(C2sp^3HO\ to\ \mathrm{S}\right)=0.64965$.

The $C-S$ group of alkyl sulfides is equivalent to that of thiols where $E_T\left(atom-atom,msp^3.AO\right)$ is $-0.72457\ eV$ (Eq. (14.151)). The t-butyl-$C-S$ group is also equivalent to that of thiols except that the energy parameters corresponding to the oscillation in the transition state are matched to those of the t-butyl group.

The symbols of the functional groups of branched-chain alkyl sulfides are given in Table 15.153. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl sulfides are given in Tables 15.154, 15.155, and 15.156, respectively. Consider that the $C-S$ bond is along the x axis in the xy-plane. The S nucleus is at the focus +c and the C nucleus is at the focus –c. The elliptic angle θ' is taken as counterclockwise from the x-axis for S and as clockwise from the –x-axis for C. The total energy of each alkyl sulfide given in Table 15.157 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.156 corresponding to functional-group composition of the molecule. E_{mag} given by Eq. (15.67) was subtracted for each t-butyl group. The bond angle parameters of alkyl sulfides determined using Eqs. (15.88-15.117) are given in Table 15.158. The color scale, translucent view of the charge-density of exemplary sulfide, dimethyl sulfide, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.26.

Figure 15.26. Color scale, translucent view of the charge-density of dimethyl sulfide showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

DISULFIDES ($C_nH_{2n+2}S_{2m},\ n=2,3,4,5...\infty$)

The alkyl disulfides, $C_nH_{2n+2}S_{2m}$, comprise $C-S$ and $S-S$ functional groups. The alkyl portion of the alkyl disulfide may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in disulfides are equivalent to those in branched-chain alkanes.

Each $C-S$ group is equivalent to that of general alkyl sulfides given in the corresponding section. As in the case of thiols and sulfides, C_2 of Eq. (15.61) for the $C-S$-bond MO given by Eq. (15.146) is $C_2\left(C2sp^3HO\ to\ \mathrm{S}\right)=0.64965$ and $E_T\left(atom-atom,msp^3.AO\right)$ is $-0.72457\ eV$ (Eq. (14.151)).

The $S-S$ group is solved as an H_2-type-ellipsoidal-MO that is energy matched to the energy of sulfur, $E(S)=-10.36001\ eV$, such that $E(AO/HO)=-10.36001\ eV$ in Eq. (15.51) with $E_T(AO/HO)=E(AO/HO)$. The $S-S$-bond MO is further energy matched to the $C2sp^3$ HO of the $C-S$-bond MO. C_2 of Eq. (15.61) for the $S-S$-bond MO given by Eq. (15.146) is also $C_2\left(C2sp^3HO\ to\ \mathrm{S}\right)=0.64965$. In order to match $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-S$ group ($-0.72457\ eV$ (Eq. (14.151))), $E_T\left(atom-atom,msp^3.AO\right)$ of the $S-S$-bond MO is determined using a linear combination of the AOs corresponding to $-0.72457\ eV$ and $0\ eV$ in Eq. (15.29), Eq. (15.31), and Eqs. (15.19-15.20). The result corresponding to bond order 1/2I in Table 15.2 is $E_T\left(atom-atom,msp^3.AO\right)=-0.36229\ eV$.

The symbols of the functional groups of branched-chain alkyl disulfides are given in Table 15.159. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl disulfides are given in Tables 15.160, 15.161, and 15.162, respectively. The total energy of each alkyl disulfide given in Table 15.163 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.162 corresponding to functional-group composition of the molecule. E_{mag} given by Eq. (15.67) was subtracted for each t-butyl group. The bond angle parameters of alkyl disulfides determined using Eqs. (15.88-15.117) are given in Table 15.164. The color scale, translucent view of the charge-density of exemplary disulfide, dimethyl disulfide, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.27.

Figure 15.27. Color scale, translucent view of the charge-density of dimethyl disulfide showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

SULFOXIDES ($C_nH_{2n+2}\left(SO\right)_m$, $n=2,3,4,5...\infty$)

The alkyl sulfoxides, $C_nH_{2n+2}\left(SO\right)_m$, comprise a $C-SO-C$ moiety that comprises $C-S$ and SO functional groups. The alkyl portion of the alkyl sulfoxide may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($\left(CH_3\right)_2CH$) and t-butyl ($\left(CH_3\right)_3C$) groups and the isop.ropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in sulfoxides are equivalent to those in branched-chain alkanes.

The electron configuration of oxygen is $1s^22s^22p^4$, and the orbital arrangement given by Eq. (10.154) has two unpaired electrons corresponding to the ground state ${}^3P_2$. The SO functional group comprises a double bond between the two unpaired electrons of O. The sulfur atom is energy matched to the $C2sp^3$ HO. In alkyl sulfoxides, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)), and the S AO has an initial energy of $E\left(S\right)=-10.36001\ eV$ [38]. To meet the equipotential condition of the union of the $S=O$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.61) for the $S=O$-bond MO given by Eqs. (15.77) and (15.79) is:

$$c_2\left(O\ to\ S3sp^3\ to\ C2sp^3HO\right)=\frac{E\left(O\right)}{E\left(S\right)}c_2\left(C2sp^3HO\right)=\frac{-13.61806\ eV}{-10.36001\ eV}\left(0.91771\right)=1.20632 \tag{15.147}$$

The S atom also forms a single bond with each of the $C2sp^3$ HOs of the two $C-S$ groups. The formation of these bonds is permitted by the hybridization of the four electrons of the $S3p$ shell to give the orbital arrangement:

$3sp^3$ state

$$\underset{0,0}{\uparrow}\quad\underset{1,-1}{\uparrow}\quad\underset{1,0}{\uparrow}\quad\underset{1,1}{\uparrow} \tag{15.148}$$

where the quantum numbers (ℓ,m_ℓ) are below each electron. The $3s$ shell remains unchanged. Then, the Coulombic energy $E_{Coulomb}\left(S,3sp^3\right)$ of the outer electron of the $S3sp^3$ shell given by Eq. (15.137) with $r_{3sp^3}=1.17585a_0$ (Eq. (15.138)) is $-11.57099\ eV$. Using Eq. (15.16) with the radius of the sulfur atom $r_{16}=1.32010a_0$ given by Eq. (10.341), the energy $E\left(S3sp^3\right)$ of the outer electron of the $S3sp^3$ shell is given by the sum of $E_{Coulomb}\left(S3sp^3\right)$ and $E(magnetic)$:

$$\begin{aligned}E\left(S3sp^3\right)&=\frac{-e^2}{8\pi\varepsilon_0r_{3sp^3}}+\frac{2\pi\mu_0e^2\hbar^2}{m_e^2r_{16}^3}=\frac{-e^2}{8\pi\varepsilon_01.17585a_0}+\frac{2\pi\mu_0e^2\hbar^2}{m_e^2\left(1.32010a_0\right)^3}\\&=-11.57099\ eV+0.04973=-11.52126\ eV\end{aligned} \tag{15.149}$$

Then, the hybridization energy $E_{hybridization}\left(S3sp^3\right)$ of the $S3sp^3$ HO is

$$E_{hybridization}\left(S3sp^3\right)=E\left(S3sp^3\right)-E\left(S\right)=-11.52126\ eV-10.36001\ eV=-1.16125\ eV \tag{15.150}$$

The SO group is matched to the $C-S$ group with which it shares the common hybridized S atom. Consequently, $E_{hybridization}\left(S3sp^3\right)$ is subtracted from $E_T\left(Group\right)$ in the determination of $E_D\left(Group\right)$ (Eq. (15.65)). Furthermore, the energy of the $S=O$-bond MO is the sum of the component energies of the H_2-type ellipsoidal MO given in Eq. (15.51) with the energy matched to the final energy of the hybridized S atom such that $E\left(AO/HO\right)=E\left(S3sp^3\right)=-11.52126\ eV$ and $\Delta E_{H_2MO}\left(AO/HO\right)=E_{hybridization}\left(S3sp^3\right)=-1.16125\ eV$. Then, $E_T\left(AO/HO\right)=E\left(S\right)=-10.36001\ eV$. Also, $E_T\left(atom-atom,msp^3.AO\right)$ of the $S=O$ bond is zero since there are no bonds with a $C2sp^3$ HO.

The $C-S$ group is solved as an energy minimum by hybridizing the $2s$ and $2p$ AOs of the C atom to form a single $2sp^3$ shell and by hybridizing the four $S3p$ electrons to form a $S3sp^3$ shell, and the sharing of electrons between the $C2sp^3$ HO and the $S3sp^3$ HO to form a MO permits each participating orbital to decrease in radius and energy. Using the Coulombic energy of the $S3sp^3$ shell, $E_{Coulomb}\left(S3sp^3\right)$ given by Eq. (15.139) in Eq. (15.72), the $S3sp^3$-shell hybridization factor, $c_2\left(S3sp^3\right)$, is:

$$c_2\left(S3sp^3\right)=\frac{E_{Coulomb}\left(S3sp^3\right)}{E\left(H\right)}=\frac{-11.57099\ eV}{-13.60580\ eV}=0.85045 \tag{15.151}$$

As in the case of thiols, sulfides, and disulfides, the energy of sulfur is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264). Thus, c_1 and c_2 are equal to one in Eq. (15.61), and the energy matching condition is determined by the C_2 parameter. In alkyl sulfoxides, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)) and the $S3sp^3$ HO has an energy of $E\left(S3sp^3\right)=-11.52126\ eV$ (Eq. (15.149)). To meet the equipotential condition of the union of the $C-S$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor C_2 of Eq. (15.61) for the $C-S$-bond MO given by Eqs. (15.77) and (15.79) is:

$$C_2\left(C2sp^3HO\ to\ S3sp^3\right)=\frac{E\left(S3sp^3\right)}{E\left(C,2sp^3\right)}c_2\left(S3sp^3\right)=\frac{-11.52126\ eV}{-14.63489\ eV}\left(0.85045\right)=0.66951 \tag{15.152}$$

As in the case of thiols, sulfides, and disulfides, with the energy of S matched to the Coulombic energy between the electron and proton of H, the energy of the $C-S$-bond MO is the sum of the component energies of the H_2-type ellipsoidal MO given in Eq. (15.51) with $E_{(AO/HO)}=0$ and $E_T\left(AO/HO\right)=\Delta E_{H_2MO}\left(AO/HO\right)$. For sulfoxides, $\Delta E_{H_2MO}\left(AO/HO\right)=-0.72457\ eV$. Further equivalently, $E_T\left(atom-atom,msp^3.AO\right)=-0.72457\ eV$ (Eq. (14.151)).

The symbols of the functional groups of branched-chain alkyl sulfoxides are given in Table 15.165. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl sulfoxides are given in Tables 15.166, 15.167, and 15.168, respectively. Consider that the $C-S$ bond is along the x axis in the xy-plane. The S nucleus is at the focus +c and the C nucleus is at the focus –c. The elliptic angle θ' is taken as counterclockwise from the x-axis for S and as clockwise from the –x-axis for C. The total energy of each alkyl sulfoxide given in Table 15.169 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.168 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl sulfoxides determined using Eqs. (15.88-15.117) are given in Table 15.170. The color scale, translucent view of the charge-density of exemplary sulfoxide, dimethyl sulfoxide, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.28.

Figure 15.28. (A)-(B) Color scale, translucent views of the charge-density of dimethyl sulfoxide showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

DIMETHYL SULFOXIDE DIHEDRAL ANGLE

The dihedral angle $\theta_{\angle S=O/CSC}$ between the plane defined by the CSC MO comprising a linear combination of two $S-C$-bond MOs and a line defined by the $S=O$-bond MO where S is the central atom is calculated using the results given in Table 15.170 and Eqs. (15.114-15.117). The distance d_1 along the bisector of $\theta_{\angle CSC}$ from S to the internuclear-distance line between C and C, $2c'_{C-C}$, is given by:

$$d_1 = 2c'_{S-C}\cos\frac{\theta_{\angle CSC}}{2} = 4.9800a_0\cos\frac{96.20°}{2} = 2.23423a_0 \tag{15.153}$$

where $2c'_{S-C}$ is the internuclear distance between S and C. The atoms C, C, and O define the base of a pyramid. Then, the pyramidal angle $\theta_{\angle COC}$ can be solved from the internuclear distances between C and C, $2c'_{C-C}$, and between C and O, $2c'_{C-O}$, using the law of cosines (Eq. (15.115)):

$$\theta_{\angle COC} = \cos^{-1}\left(\frac{\left(2c'_{C-O}\right)^2+\left(2c'_{C-O}\right)^2-\left(2c'_{C-C}\right)^2}{2\left(2c'_{C-O}\right)\left(2c'_{C-O}\right)}\right) = \cos^{-1}\left(\frac{(4.95984)^2+(4.95984)^2-(4.9800)^2}{2(4.95984)(4.95984)}\right) = 60.27° \tag{15.154}$$

Then, the distance d_2 along the bisector of $\theta_{\angle COC}$ from O to the internuclear-distance line $2c'_{C-C}$, is given by:

$$d_2 = 2c'_{C-O}\cos\frac{\theta_{\angle COC}}{2} = 4.95984a_0\cos\frac{60.27°}{2} = 4.28952a_0 \tag{15.155}$$

The lengths d_1, d_2, and $2c'_{S=O}$ define a triangle wherein the angle between d_1 and the internuclear distance between O and S, $2c'_{S=O}$, is the dihedral angle $\theta_{\angle S=O/CSC}$ that can be solved using the law of cosines (Eq. (15.117)).

$$\theta_{\angle S=O/CSC} = \cos^{-1}\left(\frac{d_1^2+\left(2c'_{S=O}\right)^2-d_2^2}{2d_1\left(2c'_{S=O}\right)}\right) = \cos^{-1}\left(\frac{(2.23423)^2+(2.81792)^2-(4.28952)^2}{2(2.23423)(2.81792)}\right) = 115.74° \tag{15.156}$$

The experimental [1] dihedral angle $\theta_{\angle S=O/CSC}$ is

$$\theta_{\angle S=O/CSC} = 115.5° \tag{15.157}$$

SULFONES ($C_nH_{2n+2}\left(SO_2\right)_m$, $n=2,3,4,5...\infty$)

The alkyl sulfones, $C_nH_{2n+2}\left(SO_2\right)_m$, comprise a $C-SO_2-C$ moiety that comprises $C-S$ and SO_2 functional groups. The alkyl portion of the alkyl sulfone may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($\left(CH_3\right)_2CH$) and t-butyl ($\left(CH_3\right)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in sulfones are equivalent to those in branched-chain alkanes.

The two unpaired electrons of each O atom form a MO with two unpaired electrons of the sulfur atom such that the MO comprises a linear combination of two bonds, each of bond order two involving the sulfur HOs and oxygen AOs of both oxygen atoms. Due to the bonding between unpaired electrons of different oxygen atoms E_{mag} (Eq. (15.68)) is subtracted from the total energy. Otherwise, the SO_2-bond MO of sulfones is solved in the same manner as the SO-bond MO of sulfoxides given in the corresponding section wherein n_1 in Eqs. (15.51) and (15.61) is four versus two. Also, the $C-S$-bond MO is equivalent to that of sulfoxides having $E_T\left(atom-atom,msp^3.AO\right)=-0.72457\ eV$ (Eq. (14.151)).

The symbols of the functional groups of branched-chain alkyl sulfones are given in Table 15.171. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl sulfones are given in Tables 15.172, 15.173, and 15.174, respectively. The total energy of each alkyl sulfone given in Table 15.165 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.174 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl sulfones determined using Eqs. (15.88-15.117) are given in Table 15.176. The color scale, translucent view of the charge-density of exemplary sulfone, dimethyl sulfone, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.29.

Figure 15.29. (A)-(B) Color scale, translucent views of the charge-density of dimethyl sulfone showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

SULFITES ($C_nH_{2n+2}\left(SO_3\right)_m$, $n=2,3,4,5...\infty$)

The alkyl sulfites, $C_nH_{2n+2}\left(SO_3\right)_m$, comprise a $C-O-SO-O-C$ moiety that comprises two types $C-O$ functional groups, one for methyl and one for alkyl, and $O-S$ and SO functional groups. The alkyl portion of the alkyl sulfite may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($\left(CH_3\right)_2CH$) and t-butyl ($\left(CH_3\right)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in sulfites are equivalent to those in branched-chain alkanes.

The SO functional group is equivalent to that of sulfoxides with $E_T\left(atom-atom,msp^3.AO\right)=0$ as given in the Sulfoxides section. The methyl and alkyl $C-O$ functional groups having $E_T\left(atom-atom,msp^3.AO\right)=-1.44915\,eV$ and $E_T\left(atom-atom,msp^3.AO\right)=-1.65376\,eV$, respectively, are equivalent to the corresponding ether groups given in the Ethers section except for the energy terms corresponding to oscillation of the bond in the transition state.

The electron configuration of oxygen is $1s^22s^22p^4$, and the orbital arrangement given by Eq. (10.154) has two unpaired electrons corresponding to the ground state ${}^3P_2$. The SO functional group comprises a double bond between the S atom and the two unpaired electrons of O. The S atom also forms single bonds with two additional oxygen atoms that are each further bound to methyl or alkyl groups. The first bond-order bonding in the $O-S$ groups is between the sulfur atom and a $O2p$ AO of each oxygen of the two bonds. The formation of these four bonds with the sulfur atom is permitted by the hybridization of the four electrons of the $S3p$ shell to give the orbital arrangement given by Eq. (15.148). Then, the Coulombic energy $E_{Coulomb}\left(S,3sp^3\right)$ of the outer electron of the $S3sp^3$ shell given by Eq. (15.139) with $r_{3sp^3}=1.17585a_0$ (Eq. (15.138)) is $-11.57099\,eV$. Using Eq. (15.16) with the radius of the sulfur atom $r_{16}=1.32010a_0$ given by Eq. (10.341), the energy $E\left(S3sp^3\right)$ of the outer electron of the $S3sp^3$ shell given by the sum of $E_{Coulomb}\left(S3sp^3\right)$ and $E(magnetic)$ is $E\left(S3sp^3\right)=-11.52126\,eV$ (Eq. (15.149)).

Thus, the $O-S$ group is solved as an energy minimum by hybridizing the four $S3p$ electrons to form a $S3sp^3$ shell, and the sharing of electrons between the $O2p$ AO and the $S3sp^3$ HO to form a MO permits each participating orbital to decrease in radius and energy. As in the case of thiols, sulfides, disulfides, and sulfoxides, the energy of sulfur is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264). Thus, c_1 and c_2 are equal to one in Eq. (15.61), and the energy matching condition is determined by the C_2 parameter. Each $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\,eV$ (Eq. (15.25)), and the S HO has an energy of $E\left(S3sp^3\right)=-11.52126\,eV$. To meet the equipotential condition of the union of the $O-S$ H_2-type-ellipsoidal-MO with these orbitals with the oxygen that further bonds to a $C2sp^3$ HO, the hybridization factor C_2 of Eq. (15.61) for the $O-S$-bond MO given by Eqs. (15.77) and (15.79) is:

$$C_2\left(S3sp^3\ to\ O\ to\ C2sp^3HO\right)=\frac{E\left(S,3sp^3\right)}{E\left(O,2p\right)}c_2\left(C2sp^3HO\right)=\frac{-11.52126\,eV}{-13.61806\,eV}\left(0.91771\right)=0.77641 \tag{15.158}$$

As in the case of thiols, sulfides, disulfides, and sulfoxides, with the energy of S matched to the Coulombic energy between the electron and proton of H, the energy of the $O-S$-bond MO is the sum of the component energies of the H_2-type ellipsoidal MO given in Eq. (15.51) with $E\left(AO/HO\right)=0$ and $E_T\left(AO/HO\right)=\Delta E_{H_2MO}\left(AO/HO\right)$. For sulfites, $\Delta E_{H_2MO}\left(AO/HO\right)=-0.92918\,eV$ and equivalently, $E_T\left(atom-atom,msp^3.AO\right)=-0.92918\,eV$ (Eq. (14.513)) due to the maximum energy match with the oxygen AO as in the case with carboxylic acid esters.

The symbols of the functional groups of branched-chain alkyl sulfites are given in Table 15.177. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl sulfites are given in Tables 15.178, 15.179, and 15.180, respectively. The total energy of each alkyl sulfite given in Table 15.175 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.180 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl sulfites determined using Eqs. (15.88-15.117) are given in Table 15.182. The color scale, translucent view of the charge-density of sulfite, dimethyl sulfite, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.30.

Figure 15.30. Color scale, translucent view of the charge-density of dimethyl sulfite showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

SULFATES ($C_nH_{2n+2}(SO_4)_m$, $n=2,3,4,5...\infty$)

The alkyl sulfates, $C_nH_{2n+2}(SO_4)_m$, comprise a $C-O-SO_2-O-C$ moiety that comprises two types $C-O$ functional groups, one for methyl and one for alkyl, and $O-S$ and SO_2 functional groups. The alkyl portion of the alkyl sulfate may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($(CH_3)_2CH$) and t-butyl ($(CH_3)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in sulfates are equivalent to those in branched-chain alkanes.

The methyl and alkyl $C-O$ functional groups having $E_T(atom-atom, msp^3.AO) = -1.44915\ eV$ and $E_T(atom-atom, msp^3.AO) = -1.65376\ eV$, respectively, are equivalent to the corresponding groups given in the Sulfites section. The $O-S$ functional group having $E_T(atom-atom, msp^3.AO) = -0.92918\ eV$ is equivalent to that given in the Sulfites section. The SO_2 functional group is equivalent to that of sulfones with $E_T(atom-atom, msp^3.AO) = 0$ as given in the Sulfones section.

The symbols of the functional groups of branched-chain alkyl sulfates are given in Table 15.183. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl sulfates are given in Tables 15.184, 15.185, and 15.186, respectively. The total energy of each alkyl sulfate given in Table 15.187 was calculated as the sum over the integer multiple of each $E_{D(Group)}$ of Table 15.186 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl sulfates determined using Eqs. (15.88-15.117) are given in Table 15.188. The color scale, translucent view of the charge-density of exemplary sulfate, dimethyl sulfate, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.31.

Figure 15.31. (A)-(B) Color scale, translucent views of the charge-density of dimethyl sulfate showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

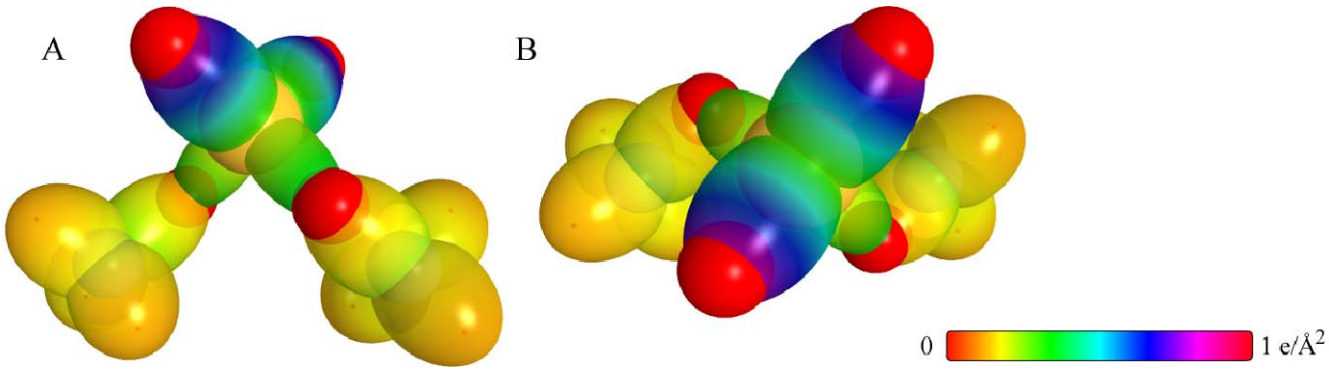

Table 15.183. The symbols of functional groups of alkyl sulfates.

Functional Group	Group Symbol
C-O (*methyl*)	$C-O$ (i)
C-O (*alkyl*)	$C-O$ (ii)
O-SO₃	$O-S$
SO₂	SO_2
CH₃ group	$C-H\ (CH_3)$
CH₂ group	$C-H\ (CH_2)$
CH	$C-H$
CC bond (*n-C*)	$C-C$ (a)
CC bond (*iso-C*)	$C-C$ (b)
CC bond (*tert-C*)	$C-C$ (c)
CC (*iso* to *iso-C*)	$C-C$ (d)
CC (*t* to *t-C*)	$C-C$ (e)
CC (*t* to *iso-C*)	$C-C$ (f)

NITROALKANES ($C_nH_{2n+2-m}\left(NO_2\right)_m$, $n=1,2,3,4,5...\infty$)

The nitroalkanes, $C_nH_{2n+2-m}\left(NO_2\right)_m$, comprise a NO_2 functional group and a $C-N$ functional group. The alkyl portion of the nitroalkane may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($\left(CH_3\right)_2CH$) and t-butyl ($\left(CH_3\right)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in nitroalkanes are equivalent to those in branched-chain alkanes.

The electron configuration of oxygen is $1s^22s^22p^4$, and the orbital arrangement given by Eq. (10.154) has two unpaired electrons corresponding to the ground state ${}^3P_2$. The electron configuration of nitrogen is $1s^22s^22p^3$, and the orbital arrangement given by Eq. (10.134) has three unpaired electrons corresponding to the ground state ${}^4S^0_{3/2}$. The bonding in the nitro (NO_2) functional group is similar to that in the SO_2 group given previously. It also has similarities to the bonding in the carbonyl functional group. In the NO_2 group, the two unpaired electrons of the O atoms form a MO with two unpaired electrons of the nitrogen atom such that the MO comprises a linear combination of two bonds, each of bond order two involving the nitrogen AOs and oxygen AOs of both oxygen atoms. The nitrogen atom is then energy matched to the $C2sp^3$ HO. In nitroalkanes, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)), the N AO has an energy of $E\left(N\right)=-14.53414\ eV$, and the O AO has an energy of $E\left(O\right)=-13.61806\ eV$ [38]. To meet the equipotential condition of the union of the $N=O$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.61) for the $N=O$-bond MO given by Eqs. (15.77) and (15.79) is:

$$c_2\left(O\ to\ N2p\ to\ C2sp^3HO\right)=\frac{E\left(O\right)}{E\left(N\right)}c_2\left(C2sp^3HO\right)=\frac{-13.61806\ eV}{-14.53414\ eV}\left(0.91771\right)=0.85987 \tag{15.159}$$

Since there are two O atoms in a linear combination that comprises the bonding of the NO_2 group, the unpaired electrons of each O cancel each others effect such that E_{mag} is not subtracted from the total energy of NO_2. Additionally, $E_T\left(atom-atom,msp^3.AO\right)=-3.71673\ eV=4\left(-0.92918\ eV\right)$ (Eq. (14.513)) is the maximum given the bonding involves four electrons comprising two bonds, each having a bond order of one.

The $C-N$ group is equivalent to that of primary amines except that the energies corresponding to vibration in the transition state are matched to a nitroalkane and $\Delta E_{H_2MO}\left(AO/HO\right)=-0.72457\ eV$ for nitroalkane and $\Delta E_{H_2MO}\left(AO/HO\right)=-1.44915\ eV$ for primary amines. Whereas, $E_T\left(atom-atom,msp^3.AO\right)=-1.44915\ eV$ for both functional groups. This condition matches the energy of the $C-N$ group with the NO_2 having $\Delta E_{H_2MO}\left(AO/HO\right)=0$.

The symbols of the functional groups of branched-chain nitroalkanes are given in Table 15.189. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of nitroalkanes are given in Tables 15.190, 15.191, and 15.192, respectively. The total energy of each nitroalkane given in Table 15.193 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.192 corresponding to functional-group composition of the molecule. E_{mag} given by Eq. (15.67) was subtracted for each t-butyl group. The bond angle parameters of nitroalkanes determined using Eqs. (15.88-15.117) are given in Table 15.194. The color scale, translucent view of the charge-density of exemplary nitroalkane, nitroethane, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.32.

Figure 15.32. Color scale, translucent view of the charge-density of nitroethane showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

ALKYL NITRITES ($C_nH_{2n+2-m}\left(NO_2\right)_m$, $n=1,2,3,4,5...\infty$)

The alkyl nitrites, $C_nH_{2n+2-m}\left(NO_2\right)_m$, comprise a $RC-O-NO$ moiety that comprises $C-O$, $O-N$, and NO functional groups. The alkyl portion of the alkyl nitrite may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($\left(CH_3\right)_2CH$) and t-butyl ($\left(CH_3\right)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl nitrites are equivalent to those in branched-chain alkanes.

The electron configuration of oxygen is $1s^22s^22p^4$, and the orbital arrangement given by Eq. (10.154) has two unpaired electrons corresponding to the ground state ${}^3P_2$. The electron configuration of nitrogen is $1s^22s^22p^3$, and the orbital arrangement given by Eq. (10.134) has three unpaired electrons corresponding to the ground state ${}^4S^0_{3/2}$. The bonding in the nitro (NO) functional group is similar to that in the SO group given previously. It also has similarities to the bonding in the carbonyl functional group. In the NO group, the two unpaired electrons of the O atom form a MO with two unpaired electrons of the nitrogen atom such that the MO comprises a double bond. The nitrogen atom is then energy matched to the $O-N$ functional group that is further energy matched to the $C2sp^3$ HO of the $C-O$ functional group. To meet the equipotential condition of the union of the $N=O$ H_2-type-ellipsoidal-MO with other orbitals of the molecule, the hybridization factor c_2 of Eq. (15.60) for the $N=O$-bond MO given by Eq. (15.159) is $c_2\left(O\ to\ N2p\ to\ C2sp^3HO\right)=0.85987$.

As in the case of the carbonyl group, two unpaired O electrons result upon bond breakage of the $N=O$ bond which requires that two times E_{mag} of oxygen (Eq. (15.68)) be subtracted from the total energy of NO. Additionally, $E_T\left(atom-atom,msp^3.AO\right)$ and $\Delta E_{H_2MO}\left(AO/HO\right)$ are equal to $-0.92918\ eV$ (Eq. (14.513)) which matches the energy of the $N=O$ bond with the contiguous $O-N$ bond and matches the energy contribution of an oxygen atom.

The $O-N$ functional group comprise a single-bond, H_2-type-ellipsoidal-MO between the remaining unpaired nitrogen electron and an unpaired electron of the second oxygen atom which further forms a single bond with the $C2sp^3$ HO of the $C-O$ functional group. In alkyl nitrites, the hybridization factor c_2 of Eq. (15.61) for the $C-O$-bond MO given by Eq. (15.133) is $c_2\left(C2sp^3HO\ to\ O\right)=0.85395$. The hybridization factor c_2 of Eq. (15.61) for a $C-N$-bond MO given by Eq. (15.135) is $c_2\left(C2sp^3HO\ to\ N\right)=0.91140$. Thus, the hybridization factor c_2 of Eq. (15.61) for $O-N$ that bridges the $C-O$ and $N=O$ bonds given by Eq. (15.78) is:

$$c_2\left(N2p\ to\ O2p\right)=\frac{c_2\left(C2sp^3HO\ to\ N\right)}{c_2\left(C2sp^3HO\ to\ O\right)}=\frac{0.91140}{0.85395}=1.06727 \tag{15.160}$$

$E_T\left(atom-atom,msp^3.AO\right)=-0.92918\ eV$ in order to match the energy of the NO group and $E\left(AO/HO\right)=-15.35946\ eV$ in order to match the $C-O$ functional group.

The $C-O$ functional group is equivalent to that of an ether as given in the corresponding section except that $E_T\left(atom-atom,msp^3.AO\right)$ and $\Delta E_{H_2MO}\left(AO/HO\right)$ are both $-0.72457\ eV$ which matches the energy contribution of an independent $C2sp^3$ HO (Eq. (14.151)). Also, the energy terms corresponding to the oscillation of the bond in the transition state are matched to a nitrite.

The symbols of the functional groups of branched-chain alkyl nitrites are given in Table 15.195. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl nitrites are given in Tables 15.196, 15.197, and 15.198, respectively. The total energy of each alkyl nitrite given in Table 15.199 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.198 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl nitrites determined using Eqs. (15.88-15.117) are given in Table 15.200. The color scale, translucent view of the charge-density of exemplary alkyl nitrite, methyl nitrite, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.33.

Figure 15.33. (A)-(B) Color scale, translucent views of the charge-density of methyl nitrite showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

ALKYL NITRATES ($C_nH_{2n+2-m}\left(NO_3\right)_m$, $n=1,2,3,4,5...\infty$)

The alkyl nitrates, $C_nH_{2n+2-m}\left(NO_3\right)_m$, comprise a $RC-O-NO_2$ moiety that comprises $C-O$, $O-N$, and NO_2 functional groups. The alkyl portion of the alkyl nitrate may comprise at least two terminal methyl groups (CH_3) at each end of the chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($\left(CH_3\right)_2CH$) and t-butyl ($\left(CH_3\right)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl nitrates are equivalent to those in branched-chain alkanes.

The NO_2 functional group is equivalent to that of nitro alkanes with the exception that $\Delta E_{H_2MO}\left(AO/HO\right)$ as well as $E_T\left(atom-atom,msp^3.AO\right)$ is equal to $-3.71673\,eV$ in order to match the group energy to that of the contiguous $O-N$ bond. Furthermore, the $O-N$ group with $E_T\left(atom-atom,msp^3.AO\right)=-0.92918\,eV$ is equivalent to that of nitrites as given in the corresponding section.

The $C-O$ functional group is equivalent to that of an ether as given in the corresponding section except that $E_T\left(atom-atom,msp^3.AO\right)$ and $\Delta E_{H_2MO}\left(AO/HO\right)$ are both $-0.92918\,eV$ which matches the energy contribution of an independent $C2sp^3$ HO (Eq. (14.513)). Also, the energy terms corresponding to the oscillation of the bond in the transition state are matched to a nitrate.

The symbols of the functional groups of branched-chain alkyl nitrates are given in Table 15.201. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl nitrates are given in Tables 15.202, 15.203, and 15.204, respectively. The total energy of each alkyl nitrate given in Table 15.205 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.204 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl nitrates determined using Eqs. (15.88-15.117) are given in Table 15.206. The color scale, translucent view of the charge-density of exemplary alkyl nitrate, ethyl nitrate, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.34.

Figure 15.34. (A)-(B) Color scale, translucent views of the charge-density of ethyl nitrate showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

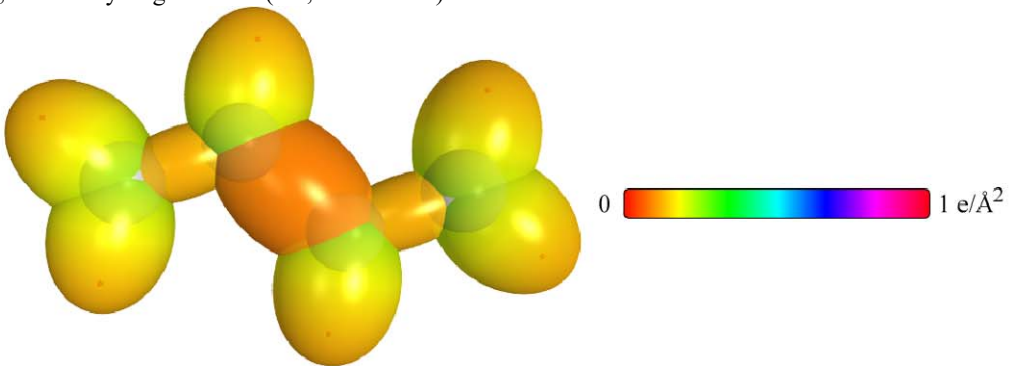
CYCLIC AND CONJUGATED ALKENES ($C_nH_{2n+2-2m-2c}$, $n=3,4,5...\infty$, $m=1,2,3...$, $c=0$ *or* 1)

The cyclic and conjugated alkenes are represented by the general formula $C_nH_{2n+2-2m-2c}$, $n=3,4,5...\infty$, $m=1,2,3...$, $c=0$ *or* 1 where m is the number of double bonds and $c=0$ for a straight-chain alkene and $c=1$ for a cyclic alkene. They have at least one carbon-carbon double bond comprising a functional group that is solved equivalently to the double bond of ethylene. Consider the cyclic and conjugated alkenes 1,3-butadiene, 1,3-pentadiene, 1,4-pentadiene, 1,3-cyclopentadiene, and cyclopentene. Based on the condition of energy matching of the orbital, any magnetic energy due to unpaired electrons in the constituent fragments, and differences in oscillation in the transition state, five distinct $C-C$ functional groups can be identified as given in Table 15.208. The designation of the structure of the groups are shown in Figures 15.35A-E. In addition, CH_2 of any $-C=CH_2$ moiety is a conjugated alkene functional group. The alkyl portion of the cyclic or conjugated alkene may comprise at least one terminal methyl group (CH_3), and may comprise methylene (CH_2), and methylyne (CH) functional groups that are equivalent to those of branched-chain alkanes.

The solution of the functional groups comprises the hybridization of the $2s$ and $2p$ AOs of each C to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ HOs to form a MO permits each participating hybridized orbital to decrease in radius and energy. The $C-C$ groups are solved in the same manner as those of the branched-chain alkanes given in the corresponding section. For example, the cyclopentene C_a-C_b group is equivalent to the n-$C-C$ alkane group. Many of the corresponding energies of the molecules of this class are similar, and they can be related to one another based on the structure. For example, cyclopentadiene is formed by ring closure of 1,3-pentadiene with the elimination of H from the terminal methyl and methylene groups. Thus, the energy of each of the corresponding carbon-carbon bonds in cyclopentadiene is the same as that in 1,3-pentadiene except that the difference between the energies of the 1,3-pentadiene C_c-C_d and the cyclopentadiene C_a-C_b groups is the magnetic energy (Eq. (15.67)) which is subtracted from the C_a-C_b total bond energy according to Eqs. (13.524-13.527) due to the formation of a CH group from the methylene group. The color scale, translucent view of the charge-density of exemplary cyclic and conjugated alkene, 1,3-butadiene, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.35.

Figure 15.35. Color scale, translucent view of the charge-density of 1,3-butadiene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).



$E_T\left(atom-atom,msp^3.AO\right)$ of the $C=C$-bond MO in Eq. (15.61) due to the charge donation from the C atoms to the MO is equivalent to that of ethylene, $-2.26759\,eV$, given by Eq. (14.247). $E_T\left(atom-atom,msp^3.AO\right)$ of each $C-C$-bond MO in Eq. (15.61) is $-2.26759\,eV$ or $-1.85836\,eV$ based on the energy match between the $C2sp^3$ HOs corresponding to the energy contributions equivalent to those of alkene, $-1.13379\,eV$ (Eq. (14.247)), or methylene, $-0.92918\,eV$ (Eq. (14.513)), groups, respectively, that are contiguous with the $C-C$-bond carbons. In the former case, the total energy of the $C-C$ bond MO is matched to that of the alkane energy in the determination of the bond length. The charge density of 0.5e must be donated to the $C-C$ bond in order to match the energy of the adjacent flanking double bonds. This further lowers the total energy of the $C-C$-bond MO and increases the $C-C$ bond energy. This additional lowering of the $C-C$-bond energy by additional charge donation over that of an alkane bond due to adjacent double bonds is called *conjugation*.

The symbols of the functional groups of cyclic and conjugated alkenes are given in Table 15.207. The structures of 1,3-butadiene, 1,3-pentadiene, 1,4-pentadiene, 1,3-cyclopentadiene, and cyclopentene are shown in Figures 15.35A-E, respectively. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of cyclic and conjugated alkenes are given in Tables 15.208, 15.209, and 15.210, respectively. The total energy of each cyclic or conjugated alkenes given in Table 15.211 was calculated as the sum over the integer multiple of each $E_D(Group)$ of

Table 15.210 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C2sp^3$ HO magnetic energy E_{mag} that is subtracted from the weighted sum of the $E_D\,(Group)$ (eV) values based on composition is given by Eq. (15.67). The bond angle parameters of cyclic and conjugated alkenes determined using Eqs. (15.88-15.117) are given in Table 15.212.

AROMATIC AND HETEROCYCLIC COMPOUNDS

Aromatic and heterocyclic molecules comprise at least one of an aromatic or a cyclic conjugated alkene functional group. The latter was described in the Cyclic and Conjugated Alkenes section. The aromatic bond is uniquely stable and requires the sharing of the electrons of multiple H_2-type MOs. The results of the derivation of the parameters of the benzene molecule given in the Benzene Molecule (C_6H_6) section can be generalized to any aromatic functional group(s) of aromatic and heterocyclic compounds.

C_6H_6 can be considered a linear combination of three ethylene molecules wherein a $C-H$ bond of each CH_2 group of $H_2C=CH_2$ is replaced by a $C=C$ bond to form a six-member ring of carbon atoms. The solution of the ethylene molecule is given in the Ethylene Molecule (CH_2CH_2) section. The radius $r_{ethylene\,2sp^3}$ ($0.85252a_0$) of the $C2sp^3$ shell of ethylene calculated from the Coulombic energy is given by Eq. (14.244). The Coulombic energy $E_{Coulomb}\left(C_{ethylene},2sp^3\right)$ ($-15.95955\,eV$) of the outer electron of the $C2sp^3$ shell is given by Eq. (14.245). The energy $E\left(C_{ethylene},2sp^3\right)$ ($-15.76868\,eV$) of the outer electron of the $C2sp^3$ shell is given by Eq. (14.246). $E_T\left(C=C,2sp^3\right)$ ($-1.13380\,eV$) (Eq. (14.247)), the energy change of each $C2sp^3$ shell with the formation of the $C=C$-bond MO is given by the difference between $E\left(C_{ethylene},2sp^3\right)$ and $E\left(C,2sp^3\right)$. C_6H_6 can be solved using the same principles as those used to solve ethylene wherein the $2s$ and $2p$ shells of each C hybridize to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ hybridized orbitals (HOs) to form a molecular orbital (MO) permits each participating hybridized orbital to decrease in radius and energy. Each $2sp^3$ HO of each carbon atom initially has four unpaired electrons. Thus, the $6H$ atomic orbitals (AOs) of benzene contribute six electrons and the six sp^3-hybridized carbon atoms contribute twenty-four electrons to form six $C-H$ bonds and six $C=C$ bonds. Each $C-H$ bond has two paired electrons with one donated from the H AO and the other from the $C2sp^3$ HO. Each $C=C$ bond comprises a linear combination of a factor of 0.75 of four paired electrons (three electrons) from two sets of two $C2sp^3$ HOs of the participating carbon atoms. Each $C-H$ and each $C=C$ bond comprises a linear combination of one and two diatomic H_2-type MOs developed in the Nature of the Chemical Bond of Hydrogen-Type Molecules and Molecular Ions section, respectively.

Consider the case where three sets of $C=C$-bond MOs form bonds between the two carbon atoms of each molecule to form a six-member ring such that the six resulting bonds comprise eighteen paired electrons. Each bond comprises a linear combination of two MOs wherein each comprises two $C2sp^3$ HOs and 75% of a H_2-type ellipsoidal MO divided between the $C2sp^3$ HOs:

$$\begin{pmatrix} 3\left(2\;C2sp^3+0.75\;H_2\;MO\right)\rightarrow 3\left(C\overset{4e}{=}C\right)-ethylene-type-bond\;MO \\ \rightarrow 6\left(C\overset{3e}{=}C\right)-bond\;MO\;of\;benzene \end{pmatrix} \tag{15.161}$$

The linear combination of each H_2-type ellipsoidal MO with each $C2sp^3$ HO further comprises an excess of 25% charge-density contribution per bond from each $C2sp^3$ HO to the $C=C$-bond MO to achieve an energy minimum. Thus, the dimensional parameters of each bond $C=C$-bond are determined using Eqs. (15.51) and (15.1-15.5) in a form that are the same equations as those used to determine the same parameters of the $C=C$-bond MO of ethylene (Eqs. (14.242-14.268)) while matching the boundary conditions of the structure of benzene.

Hybridization with 25% electron donation to each $C=C$-bond gives rise to the $C_{benzene}2sp^3$ HO-shell Coulombic energy $E_{Coulomb}\left(C_{benzene},2sp^3\right)$ given by Eq. (14.245). To meet the equipotential condition of the union of the six $C2sp^3$ HOs, c_2 and C_2 of Eq. (15.51) for the aromatic $C\overset{3e}{=}C$-bond MO is given by Eq. (15.71) as the ratio of $15.95955\,eV$, the magnitude of $E_{Coulomb}\left(C_{benzene},2sp^3\right)$ (Eq. (14.245)), and $13.605804\,eV$, the magnitude of the Coulombic energy between the electron and proton of H (Eq. (1.264)):

$$C_2\left(benzeneC2sp^3HO\right)=c_2\left(benzeneC2sp^3HO\right)=\frac{13.605804\;eV}{15.95955\;eV}=0.85252 \tag{15.162}$$

The energies of each $C\overset{3e}{=}C$ bond of benzene are also determined using the same equations as those of ethylene (Eqs. (14.251-14.253) and (14.319-14.333)) with the parameters of benzene. Ethylene serves as a basis element for the $C\overset{3e}{=}C$ bonding of benzene wherein each of the six $C\overset{3e}{=}C$ bonds of benzene comprises (0.75)(4) = 3 electrons according to Eq. (15.161). The total energy of the bonds of the eighteen electrons of the $C\overset{3e}{=}C$ bonds of benzene, $E_T\left(C_6H_6,C\overset{3e}{=}C\right)$, is given by (6)(0.75) times $E_{T+osc}(C=C)$ (Eq. (14.492)), the total energy of the $C\overset{3e}{=}C$-bond MO of benzene including the Doppler term, minus eighteen times $E\left(C,2sp^3\right)$ (Eq. (14.146)), the initial energy of each $C2sp^3$ HO of each C that forms the $C\overset{3e}{=}C$ bonds of bond order two.

Thus, the total energy of the six $C\overset{3e}{=}C$ bonds of benzene with three electron per aromatic bond given by Eq. (14.493) is:

$$\begin{aligned} E_T\left(C_6H_6, C\overset{3e}{=}C\right) &= (6)(0.75)E_{T+osc}\left(C=C\right)-(6)(3)E\left(C,2sp^3\right) \\ &= (6)(0.75)(-66.05796\ eV)-18(-14.63489\ eV) \\ &= -297.26081\ eV-(-263.42798\ eV) = -33.83284\ eV \end{aligned} \tag{15.163}$$

The results of benzene can be generalized to the class of aromatic and heterocyclic compounds. $E_{h\nu}$ of an aromatic bond is given by $E_T\left(H_2\right)$ (Eqs. (11.212) and (14.486)), the maximum total energy of each H_2-type MO such that:

$$\bar{E}_{osc} = n_1\left(\bar{E}_D+\bar{E}_{Kvib}\right) = n_1\left(-31.63536831\ eV\sqrt{\frac{2\bar{E}_K}{Mc^2}}+\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}\right) \tag{15.164}$$

The factor of 0.75 corresponding to the three electrons per aromatic bond of bond order two given in the Benzene Molecule (C_6H_6) section modifies Eqs. (15.61-15.65). Multiplication of the total energy given by Eq. (15.64) by $f_1=0.75$ with the substitution of Eq. (15.164) gives the total energy of the aromatic bond:

$$E_T\left(Group\right) = f_1\begin{pmatrix} E(basis\ energies)+E_T\left(atom-atom, msp^3.AO\right) \\ -31.63536831\ eV\sqrt{\dfrac{2\hbar\sqrt{\dfrac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0R^3}}}{m_ec^2}}+n_1\bar{E}_{Kvib}+c_3\dfrac{8\pi\mu_0\mu_B^2}{r^3} \end{pmatrix} \tag{15.165}$$

The total bond energy of the aromatic group $E_D\left(Group\right)$ is the negative difference of the total energy of the group (Eq. (15.165)) and the total energy of the starting species given by the sum of $c_4E_{initial}\left(c_4\ AO/HO\right)$ and $c_5E_{initial}\left(c_5\ AO/HO\right)$:

$$E_D\left(Group\right) = -\begin{pmatrix} f_1\begin{pmatrix} E(basis\ energies)+E_T\left(atom-atom, msp^3.AO\right) \\ -31.63536831\ eV\sqrt{\dfrac{2\hbar\sqrt{\dfrac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_0R^3}}}{m_ec^2}}+n_1\bar{E}_{Kvib}+c_3\dfrac{8\pi\mu_0\mu_B^2}{r^3} \end{pmatrix} \\ -\left(c_4E_{initial}\left(AO/HO\right)+c_5E_{initial}\left(c_5\ AO/HO\right)\right) \end{pmatrix} \tag{15.166}$$

Since there are three electrons per aromatic bond, c_4 is three times the number of aromatic bonds.

Benzene can also be considered as comprising chemical bonds between six *CH* radicals wherein each radical comprises a chemical bond between carbon and hydrogen atoms. The solution of the parameters of *CH* is given in the Hydrogen Carbide (CH) section. Those of the benzene are given in the Benzene Molecule (C_6H_6) section. The energy components of V_e, V_p, T, V_m, and E_T are the same as those of the hydrogen carbide radical, except that $E_T\left(C=C,2sp^3\right)=-1.13379\ eV$ (Eq. (14.247)) is subtracted from $E_T\left(CH\right)$ of Eq. (13.495) to match the energy of each $C-H$-bond MO to the decrease in the energy of the corresponding $C2sp^3$ HO. In the corresponding generalization of the aromatic CH group, the geometrical parameters are determined using Eq. (15.51) and Eqs. (15.1-15.5) with $E_T\left(atom-atom, msp^3.AO\right)=-1.13379\ eV$.

The total energy of the benzene $C-H$-bond MO, $E_{T_{benzene}}\left(C-H\right)$, given by Eq. (14.467) is the sum of $0.5E_T\left(C=C,2sp^3\right)$, the energy change of each $C2sp^3$ shell per single bond due to the decrease in radius with the formation of the corresponding $C\overset{3e}{=}C$-bond MO (Eq. (14.247)), and $E_{T_{benzene}}\left(CH\right)$, the σ MO contribution given by Eq. (14.441). In the corresponding generalization of the aromatic *CH* group, the energy parameters are determined using Eqs. (15.165-15.166) with $f_1=1$ and $E_T\left(atom-atom, msp^3.AO\right)=\dfrac{-1.13379\ eV}{2}$. Thus, the energy contribution to the single aromatic CH bond is one half that of the $C\overset{3e}{=}C$ double bond contribution. This matches the energies of the CH and $C\overset{3e}{=}C$ aromatic groups, conserves the electron number with the equivalent charge density as that of $s=1$ in Eqs. (15.18-15.21), and further gives a minimum energy for the molecule. Breakage of the aromatic $C\overset{3e}{=}C$ bonds to give CH groups creates unpaired electrons in these fragments that corresponds to $c_3=1$ in Eq. (15.65) with E_{mag} given by Eq. (15.67).

Each of the $C-H$ bonds of benzene comprises two electrons according to Eq. (14.439). From the energy of each $C-H$ bond, $-E_{D_{benzene}}\left({}^{12}CH\right)$ (Eq. (14.477)), the total energy of the twelve electrons of the six $C-H$ bonds of benzene, $E_T\left(C_6H_6,C-H\right)$, given by Eq. (14.494) is:

$$E_T\left(C_6H_6,C-H\right)=(6)\left(-E_{D_{benzene}}\left({}^{12}CH\right)\right)=6\left(-3.90454\ eV\right)=-23.42724\ eV \tag{15.167}$$

The total bond dissociation energy of benzene, $E_D\left(C_6H_6\right)$, given by Eq. (14.495) is the negative sum of $E_T\left(C_6H_6,C\overset{3e}{=}C\right)$ (Eq. (14.493)) and $E_T\left(C_6H_6,C-H\right)$ (Eq. (14.494)):

$$E_D\left(C_6H_6\right)=-\left(E_T\left(C_6H_6,C\overset{3e}{=}C\right)+E_T\left(C_6H_6,C-H\right)\right)=-\left(\left(-33.83284\ eV\right)+\left(-23.42724\ eV\right)\right)=57.2601\ eV \tag{15.168}$$

Using the parameters given in Tables 15.214 and 15.216 in the general equations (Eqs. (15.51), (15.1-15.5), and (15.165-15.166)) reproduces the results for benzene given in the Benzene Molecule (C_6H_6) section as shown in Tables 15.214 and 15.216.

The symbols of the functional groups of aromatics and heterocyclics are given in Table 15.213. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of aromatics and heterocyclics are given in Tables 15.214, 15.215, and 15.216, respectively. The total energy of benzene given in Table 15.217 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.216 corresponding to functional-group composition of the molecule. The bond angle parameters of benzene determined using Eqs. (15.88-15.117) are given in Table 15.218. The color scale, translucent view of the charge-density of exemplary aromatic, benzene, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.36.

Figure 15.36. Color scale, translucent view of the charge-density of benzene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

NAPHTHALENE

Naphthalene has the formula $C_{10}H_8$ and comprises a planar molecule with two aromatic rings that share a common $C-C$ group. In order to be aromatic, the total number of bonding electrons must be a multiple of 3 since the number of electrons of the aromatic bond is $(0.75)(4)=3$ as shown in the Benzene section. In the case of naphthalene, the peripheral 10 carbons form the aromatic MO with the center bridged by a $C-C$ single bond. Then, 30 electrons of the 48 available form aromatic bonds, two electrons form the bridging $C-C$ single bond, and 16 electrons form the eight $C-H$ single bonds. The energies of the aromatic carbons are given by the same equations as those of benzene (Eqs. (15.51), (15.1-15.5), and (15.165-15.166)), except that there are 10 in naphthalene versus six in benzene. Since there are three electrons per aromatic bond, c_4 is three times ten, the number of aromatic bonds. Similarly, the aromatic $C-H$ group of naphthalene is equivalent to that of benzene.

To meet the equipotential condition of the union of the ten $C2sp^3$ HOs bridged by the $C-C$ single bond, the parameters c_1, C_2, and C_{2o} of Eq. (15.51) are one for the $C-C$ group, C_{1o} and C_1 are 0.5, and c_2 given by Eq. (15.161) is $c_2\left(C2sp^3HO\right)=0.85252$. Otherwise, the solutions of the $C-C$ bond parameters are equivalent to those of the replaced $C-H$ groups with $E\left(AO/HO\right)=-14.63489\ eV$ and $\Delta E_{H_2MO}\left(AO/HO\right)=-1.13379\ eV$ per carbon in Eq. (15.51). Similarly, the energy parameters are determined using Eqs. (15.61-15.65) with $E_T\left(atom-atom,msp^3.AO\right)=\dfrac{-1.13379\ eV}{2}$.

The symbols of the functional groups of naphthalene are given in Table 15.219. The corresponding designation of the structure is shown in Figure 15.37B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of naphthalene are given in Tables 15.220, 15.221, and 15.222, respectively. The total energy of naphthalene given in Table 15.223 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.222 corresponding to functional-group composition of the molecule. The bond angle parameters of naphthalene determined using Eqs. (15.88-15.117) are given in Table 15.224. The color scale, translucent view of the charge-density of naphthalene, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.37A. The polycyclic aromatic hydrocarbon pentacene was imaged by atomic force microscopy using a single CO molecule as the probe [53]. The resulting breakthrough in resolution revealed that in contrast to the fuzzy images touted by quantum theoreticians as proof of the cloud model of the electron, the images showed localized bonding MOs and AOs in agreement with the classical solution as shown in Figure 15.38.

Figure 15.37. (A) Color scale, translucent view of the charge-density of naphthalene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of naphthalene.

TOLUENE

Toluene has the formula C_7H_8 and comprises the benzene molecule with one hydrogen atom replaced by a methyl group corresponding to a CH_3 functional group and a $C-C$ functional group. The aromatic $C\overset{3e}{=}C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The CH_3 functional group is the same as that of continuous and branched-chain alkanes given in the corresponding sections.

The bond between the methyl and aromatic ring comprises a $C-C$ functional group that is solved using the same principles as those used to solve the alkane functional groups wherein the $2s$ and $2p$ AOs of each C hybridize to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ HOs to form a MO permits each participating hybridized orbital to decrease in radius and energy. To match energies within the MO that bridges methyl and aromatic carbons, $E(AO/HO)$ and $\Delta E_{H_2MO}(AO/HO)$ in Eq. (15.50) are $-15.35946\ eV$ (Eq. (14.155)) and $\frac{-1.13379\ eV}{2}$, respectively.

To meet the equipotential condition of the union of the aromatic and methyl $C2sp^3$ HOs of the $C-C$ single bond, the parameters c_1, C_2, and C_{2o} of Eq. (15.51) are one for the $C-C$ group, C_{1o} and C_1 are 0.5, and c_2 given by Eq. (13.430) is $c_2\left(C2sp^3HO\right)=0.91771$. To match the energies of the functional groups, $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-C$-bond MO in Eq. (15.61) due to the charge donation from the C atoms to the MO is $-1.13379\ eV$ which is the same energy per $C2sp^3$ HO as that of the replaced $C-H$ group.

The symbols of the functional groups of toluene are given in Table 15.225. The corresponding designation of the structure is shown in Figure 15.39B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of toluene are given in Tables 15.226, 15.227, and 15.228, respectively. The total energy of toluene given in Table 15.229 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.228 corresponding to functional-group composition of the molecule. The bond angle parameters of toluene determined using Eqs. (15.88-15.117) are given in Table 15.230. The color scale, translucent view of the charge-density of toluene comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.39A.

Figure 15.39. (A) Color scale, translucent view of the charge-density of toluene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of toluene.

HALOBENZENES

Halobenzenes have the formula $C_6H_{6-m}X_m$ $X=F,Cl,Br,I$ and comprise the benzene molecule with at least one hydrogen atom replaced by a halogen atom corresponding to a $C-X$ functional group. The aromatic $C\overset{3e}{=}C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The hybridization factors of the aryl $C-X$ functional groups are equivalent to those of the corresponding alkyl halides as given in Tables 15.30, 15.36, 15.42, and 15.48, and are solved using the same principles as those used to solve the alkyl halide functional groups as given in the corresponding sections. In each case, the $2s$ and $2p$ AOs of each C hybridize to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and X AO to form a MO permits each participating hybridized orbital to decrease in radius and energy. Therefore, the MO is energy matched to the $C2sp^3$ HO such that $E\left(AO/HO\right)$ in Eq. (15.51) is $-14.63489\,eV$. $E_T\left(atom-atom,msp^3.AO\right)$ of each $C-X$ functional group given in Table 15.234 that achieves matching of the energies of the AOs and HOs within the functional groups of the MOs are those of alkanes and alkenes given in Tables 15.1 and 15.2. To further match energies within each MO that bridges the halogen AO and aromatic carbon $C2sp^3$ HO, $\Delta E_{H_2MO}\left(AO/HO\right)$ in Eq. (15.51) is $E_T\left(atom-atom,msp^3.AO\right)$ of the alkene $C=C$ functional group, $-2.26759\,eV$ given by Eq. (14.247), plus the maximum possible contribution of $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-X$ functional group to minimize the energy of the MO as given in Table 15.234. $E_{initial}\left(c_4\ AO/HO\right)$ is $-14.63489\,eV$ (Eq. (15.25)), except for $C-I$ due to the low ionization potential of the I AO. In order to achieve an energy minimum with energy matching within iodo-aryl molecules, $E_{initial}\left(c_4\ AO/HO\right)$ of the $C-I$ functional group is $-15.76868\,eV$ (Eq. (14.246)), and $E_T\left(atom-atom,msp^3.AO\right)$ is $-1.65376\,eV$ given by the linear combination of $-0.72457\,eV$ (Eq. (14.151)) and $-0.92918\,eV$ (Eq. (14.513)), respectively.

The small differences between energies of ortho, meta, and para-dichlorobenzene is due to differences in the energies of vibration in the transition state that contribute to E_{osc}. Two types of $C-Cl$ functional groups can be identified based on symmetry that determine the parameter R in Eq. (15.57). One corresponds to the special case of 1,3,5 substitution and the other corresponds to other cases of single or multiple substitutions of Cl for H. P-dichlorobenzene is representative of the bonding with $R=a$. 1,2,3-trichlorobenzene is the particular case wherein $R=b$. Also, beyond the binding of three chlorides E_{mag} is subtracted for each additional Cl due to the formation of an unpaired electrons on each $C-Cl$ bond.

The symbols of the functional groups of halobenzenes are given in Table 15.231. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of halobenzenes are given in Tables 15.232, 15.233, and 15.234, respectively. The total energy of each halobenzene given in Table 15.235 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.234 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C2sp^3$ HO magnetic energy E_{mag} that is subtracted from the weighted sum of the $E_{D\,(Group)}$ (eV) values based on composition is given by Eq. (15.67). The bond angle parameters of halobenzenes determined using Eqs. (15.88-15.117) are given in Table 15.236. The color scale, translucent view of the charge-density of chlorobenzene comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.40.

Figure 15.40. Color scale, translucent view of the charge-density of chlorobenzene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

PHENOL

Phenol has the formula C_6H_6O and comprises the benzene molecule with one hydrogen atom replaced by a hydroxyl corresponding to an OH functional group and a $C-O$ functional group. The aromatic $C\overset{3e}{=}C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The OH functional group is the same as that of alcohols given in the corresponding section.

The bond between the hydroxyl and aromatic ring comprises a $C-O$ functional group that is solved using the same principles as those used to solve the alcohol functional groups wherein the $2s$ and $2p$ AOs of each C hybridize to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and O AO to form a MO permits each participating hybridized orbital to decrease in radius and energy. In aryl alcohols, the aromatic $C2sp^3$ HO has a hybridization factor of 0.85252 (Eq. (15.162)) with an initial energy of $E\left(C,2sp^3\right)=-14.63489\,eV$ (Eq. (15.25)) and the O AO has an energy of $E(O)=-13.61806\,eV$. To meet the equipotential condition of the union of the $C-O$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.61) for the $C-O$-bond MO given by Eqs. (15.77) and (15.79) is:

$$c_2\left(arylC2sp^3HO\ to\ O\right)=\frac{E(O)}{E\left(C,2sp^3\right)}c_2\left(arylC2sp^3HO\right)=\frac{-13.61806\,eV}{-14.63489\,eV}(0.85252)=0.79329 \tag{15.169}$$

$E_T\left(atom-atom,msp^3.AO\right)$ of the $C-O$-bond MO in Eq. (15.61) due to the charge donation from the C and O atoms to the MO is $-1.49608\,eV$. It is based on the energy match between the OH group and the $C2sp^3$ HO of an aryl group and is given by the linear combination of $-0.92918\,eV$ (Eq. (14.513)) and $-1.13379\,eV$ (Eq. (14.247)), respectively.

The symbols of the functional groups of phenol are given in Table 15.237. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of phenol are given in Tables 15.238, 15.239, and 15.240, respectively. The total energy of phenol given in Table 15.241 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.240 corresponding to functional-group composition of the molecule. The bond angle parameters of phenol determined using Eqs. (15.88-15.117) are given in Table 15.242. The color scale, translucent view of the charge-density of phenol comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.41.

Figure 15.41. Color scale, translucent view of the charge-density of phenol showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

ANILINE

Aniline and methyl aniline have the formula C_6H_7N and C_7H_9N, respectively. They comprise the benzene and toluene molecules with one hydrogen atom replaced by an amino group corresponding to an NH_2 functional group and a $C-N$ functional group. The aromatic $C\overset{3e}{=}C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The $C-C$ and CH_3 functional groups of methyl anilines are equivalent to those of toluene given in the corresponding section.

The aryl amino (NH_2) functional group was solved using the procedure given in the Dihydrogen Nitride (NH_2) section. Using the results of Eqs. (13.245-13.368), the aryl amino parameters in Eq. (15.60) are $n_1=2$, $C_1=0.75$, $C_2=0.93613$ (Eqs. (13.248-13.249)), $C_{1o}=1.5$, and $c_1=0.75$. In the determination of the hybridization factor c_2 of Eq. (15.61) for the $N-H$ -bond MO of aryl amines, the $C2sp^3$ HO of the $C-NH_2$ -bond MO has an energy of $E\left(C,2sp^3\right)=-15.76868\ eV$ (Eq. (15.18)) corresponding to $s=2$ in Eqs. (15.18-15.20), and the N AO has an energy of $E(N)=-14.53414\ eV$. To meet the equipotential condition of the union of the $N-H$ H_2-type-ellipsoidal-MO with the $C2sp^3$ HO, the hybridization factor c_2 given by Eq. (15.77) is:

$$c_2\left(H\ to\ aniline\ N\right)=\frac{E(N)}{E\left(C,2sp^3\right)}=\frac{-14.53414\ eV}{-15.76868\ eV}=0.92171 \tag{15.170}$$

The bond between the amino and aromatic ring comprises a $C-N$ functional group that is the same as that of 2° amines (methylene) except that the energies corresponding to oscillation in the transition state are those of aniline. The group is solved using the same principles as those used to solve the primary and secondary-amine functional groups wherein the $2s$ and $2p$ AOs of each C hybridize to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and N AO to form a MO permits each participating hybridized orbital to decrease in radius and energy. The hybridization is determined in a similar manner to that of the $C-O$ group of phenol. In anilines, the aromatic $C2sp^3$ HO has a hybridization factor of 0.85252 (Eq. (15.162)) with an initial energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)) and the N AO has an energy of $E(N)=-14.53414\ eV$. To meet the equipotential condition of the union of the $C-N$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.60) for the $C-N$ -bond MO given by Eqs. (15.77) and (15.79) is:

$$\begin{aligned} c_2\left(arylC2sp^3HO\ to\ N\right)&=\frac{E(N)}{E\left(C,2sp^3\right)}c_2\left(arylC2sp^3HO\right)\\ &=\frac{-14.53414\ eV}{-14.63489\ eV}(0.85252)\\ &=0.84665 \end{aligned} \tag{15.171}$$

$E_T\left(atom-atom,msp^3.AO\right)$ of the $C-N$ -bond MO in Eq. (15.61) due to the charge donation from the C and N atoms to the MO is $-1.13379\ eV$ (Eq. (14.247)). It is based on the energy match between the NH_2 group and the $C2sp^3$ HO of the aryl group and is twice that of the aryl $C-H$ group that it replaces.

The symbols of the functional groups of aniline and methyl-substituted anilines are given in Table 15.243. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of aniline and methyl-substituted anilines are given in Tables 15.244, 15.245, and 15.246, respectively. The total energy of each aniline and methyl-substituted aniline given in Table 15.247 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.246 corresponding to functional-group composition of the molecule. The bond angle parameters of aniline and methyl-substituted anilines determined using Eqs. (15.88-15.117) are given in Table 15.248. The color scale, translucent view of the charge-density of aniline comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.42.

Figure 15.42. Color scale, translucent view of the charge-density of aniline showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

ARYL NITRO COMPOUNDS

Aryl nitro compounds have a hydrogen of an aryl group replaced by a nitro corresponding to an NO_2 functional group and a $C-N$ functional group. Examples include nitrobenzene, nitrophenol, and nitroaniline with formulas $C_6H_5NO_2$, $C_6H_5NO_3$, and $C_6H_6N_2O_2$, respectively. The aromatic $C\overset{3e}{=}C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The OH and $C-O$ functional groups of nitrophenols are the same as those of phenol given in the corresponding section. The NH_2 and $C-N$ functional groups of nitroanilines are the same as those of aniline given in the corresponding section. The differences between the total bond energies of the nitroanilines given in Table 15.252 are due to differences in the E_{osc} term. For simplicity and since the differences are small, the E_{osc} terms for nitroanilines were taken as the same.

The NO_2 group is the same as that given in the Nitroalkanes section. The bond between the nitro and aromatic ring comprises a $C-N$ functional group that is the same as that of nitroalkanes given in the corresponding section except that $E_T\left(atom-atom, msp^3.AO\right)$ is $-0.72457\ eV$, one half of that of the $C-N$ -bond MO of nitroalkanes and equivalent to that of methyl (Eq. (14.151)) in order to maintain the independence and aromaticity of the benzene functional group. In addition, the energy terms due to oscillation in the transition state correspond to those of an aryl nitro compound.

The symbols of the functional groups of aryl nitro compounds are given in Table 15.249. The geometrical (Eqs. (15.1-15.5) and (15.42)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of aryl nitro compounds are given in Tables 15.250, 15.251, and 15.252, respectively. The total energy of each aryl nitro compound given in Table 15.253 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.252 corresponding to functional-group composition of the molecule. For each set of unpaired electrons created by bond breakage, the $C2sp^3$ HO magnetic energy E_{mag} that is subtracted from the weighted sum of the $E_D(Group)$ (eV) values based on composition is given by Eq. (15.67). The bond angle parameters of aryl nitro compounds determined using Eqs. (15.88-15.117) are given in Table 15.254. The color scale, translucent view of the charge-density of exemplary aryl nitro, nitrobenzene, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.43.

Figure 15.43. Color scale, translucent view of the charge-density of nitrobenzene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

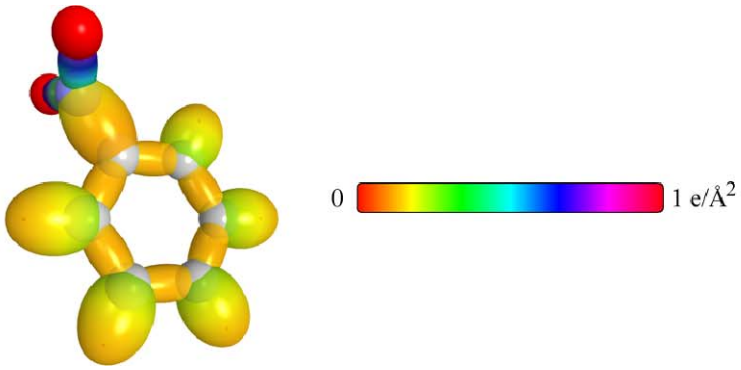

Table 15.249. The symbols of functional groups of aryl nitro compounds.

Functional Group	Group Symbol
CC (aromatic bond)	$C\overset{3e}{=}C$
CH (aromatic)	CH (i)
Aryl C-N (aniline)	$C-N$ (a)
Aryl C-N (nitro)	$C-N$ (b)
Aryl C-O	$C-O$ (a)
NO_2 group	NO_2
NH_2 group	NH_2
OH group	OH

BENZOIC ACID COMPOUNDS

Benzoic acid compounds have a hydrogen of an aryl group replaced by a carboxylic acid group corresponding to an $C-C(O)-OH$ moiety that comprises $C=O$ and OH functional groups that are the same as those of carboxylic acids given in the corresponding section. The single bond of aryl carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. This group is also equivalent to the same group of carboxylic acids except that $\Delta E_{H_2MO}\left(AO/HO\right)$ in Eq. (15.51) and $E_T\left(atom-atom,msp^3.AO\right)$ in Eq. (15.61) are both $-1.29147\,eV$ which is a linear combination of $\frac{-1.13379\,eV}{2}$, $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-H$ group that the $C-C(O)$ group replaces, and that of an independent $C2sp^3$ HO, $-0.72457\,eV$ (Eq. (14.151)).

Examples include benzoic acid, chlorobenzoic acid, and aniline carboxylic acid with formulas $C_7H_6O_2$, $C_7H_5O_2Cl$, and $C_7H_7NO_2$, respectively. The aromatic $C\overset{3e}{=}C$ and $C-H$ functional groups are equivalent to those of benzene given in Aromatic and Heterocyclic Compounds section. The NH_2 and $C-N$ functional groups of aniline carboxylic acids are the same as those of aniline given in the corresponding section. The $C-Cl$ functional group of 2-chlorobenzoic acids corresponding to meta substitution is equivalent to that of chlorobenzene given in the corresponding section. The $C-Cl$ functional group of 3 or 4-chlorobenzoic acids corresponding to ortho and para substitution is also equivalent to that of chlorobenzene, except that $E_T\left(atom-atom,msp^3.AO\right)$ in Eq. (15.61) is $-0.92918\,eV$ (Eq. (14.513)) for both cases since each of these positions can form a resonance structure with the carboxylic acid group which is permissive of greater charge donation from the $C2sp^3$ HO.

The symbols of the functional groups of benzoic acid compounds are given in Table 15.255. The corresponding designations of benzoic acid is shown in Figure 15.44B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of benzoic acid compounds are given in Tables 15.256, 15.257, and 15.258, respectively. The total energy of each benzoic acid compound given in Table 15.259 was calculated as the sum over the integer multiple of each $E_D\left(Group\right)$ of Table 15.258 corresponding to functional-group composition of the molecule. The bond angle parameters of benzoic acid compounds determined using Eqs. (15.88-15.117) are given in Table 15.260. The color scale, translucent view of the charge-density of benzoic acid comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.44A.

Figure 15.44. (A) Color scale, translucent view of the charge-density of benzoic acid showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of benzoic acid.

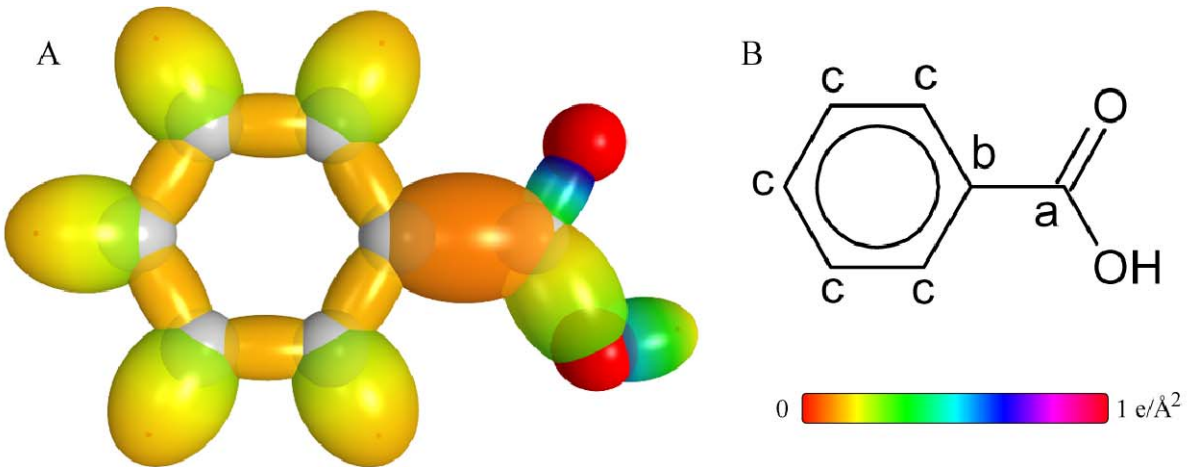

Table 15.255. The symbols of functional groups of benzoic acid compounds.

Functional Group	Group Symbol
CC (aromatic bond)	$C\overset{3e}{=}C$
CH (aromatic)	*CH* (i)
C-*C*(*O*)	$C-C(O)$
C=*O* (aryl carboxylic acid)	$C=O$
(*O*)*C*-*O*	$C-O$
OH group	OH
$Cl-C$ (*Cl* to aromatic bond of 2-chlorobenzoic acid)	$C-Cl$ (i)
$Cl-C$ (*Cl* to aromatic bond of 3 or 4-chlorobenzoic acid)	$C-Cl$ (ii)
Aryl *C*-*N* (aniline)	$C-N$
NH_2 group	NH_2

ANISOLE

Anisole has the formula C_7H_8O and comprises the phenol molecule with the hydroxyl hydrogen atom replaced by the moiety $-O-CH_3$ to form an ether comprising aromatic and methyl functional groups as well as two types of $C-O$ functional groups, one for aryl carbon to oxygen and one for methyl carbon to oxygen. The aromatic $C\overset{3e}{=}C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The CH_3 and methyl $C-O$ functional groups are the same as those of the corresponding ether groups given in the corresponding section.

The $C-O$ functional group comprising the bond between the ether oxygen and aromatic ring is equivalent to that of the methyl ether $C-O$ functional group except that $\Delta E_{H_2MO}\left(AO/HO\right)$ in Eq. (15.51) and $E_T\left(atom-atom,msp^3.AO\right)$ in Eq. (15.61) are both $-1.13379\,eV$ (Eq. (14.247)). $E_T\left(atom-atom,msp^3.AO\right)$ is based on the energy match between the OCH_3 group and the $C2sp^3$ HO of the aryl group and is twice that of the aryl $C-H$ group that it replaces.

The symbols of the functional groups of anisole are given in Table 15.261. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of anisole are given in Tables 15.262, 15.263, and 15.264, respectively. The total energy of anisole given in Table 15.265 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.264 corresponding to functional-group composition of the molecule. The bond angle parameters of anisole determined using Eqs. (15.88-15.117) are given in Table 15.266. The color scale, translucent view of the charge-density of anisole comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.45.

Figure 15.45. Color scale, translucent view of the charge-density of anisole showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

PYRROLE

Pyrrole having the formula C_4H_5N comprises the conjugated alkene 1,3-butadiene that forms a cyclic structure by terminal-atom bonding to a NH functional group. The two symmetrical carbon-to-nitrogen bonds comprise the $C-N-C$ functional group. The 1,3-butadiene moiety comprises $C-C$, $C=C$, and CH functional groups. The $C-C$ and $C=C$ groups are equivalent to the corresponding groups of 1,3-butadiene given in the Cyclic and Conjugated Alkenes section except that the energy terms corresponding to oscillation in the transition state match pyrrole. Furthermore, the conjugated double bonds have the same bonding as in 1,3-butadiene except that the hybridization terms c_2 of the $C-C$ and $C=C$ groups and C_2 and C_{2o} of the $C=C$ group in Eqs. (15.51) and (15.61) become that of benzene given by Eq. (15.162), $(C_2\left(benzeneC2sp^3HO\right)=c_2\left(benzeneC2sp^3HO\right)=0.85252)$, in the cyclic pyrrole MO which has aromatic character. The bonding in pyrrole, furan, and thiophene are the same except for the energy match to the corresponding heteroatoms. The hybridization permits double-bond character in the carbon-heteroatom bonding.

The NH group is solved equivalently to that of a secondary amine as given in the corresponding section except that the hybridization term c_2 is that of the amino group of aniline in order provide double-bond character to match the group to the other orbitals of the molecule. Similarly, the CH functional group is equivalent to that of 1,3-butadiene, except that $\Delta E_{H_2MO}\left(AO/HO\right)=-2.26758\ eV$ (Eq. (14.247)) in Eq. (15.51) in order to provide matching double-bond character.

The solution of the $C-N-C$ functional group comprises the hybridization of the $2s$ and $2p$ AOs of each C to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ HOs and the nitrogen atom to form a MO permits each participating hybridized orbital to decrease in radius and energy. Thus, the $C-N-C$ -bond MO comprising a linear combination of two single bonds is solved in the same manner as a double bond with $n_1=2$ in Eqs. (15.51) and (15.61). The hybridization factor $c_2\left(arylC2sp^3HO\ to\ N\right)=0.84665$ (Eq. (15.171)) matches the double-bond character of the $C2sp^3$ HOs to the N atom of the NH group, and C_2 and C_{2o} in Eqs. (15.51) and (15.61) become that of benzene given by Eq. (15.162), $C_2\left(benzeneC2sp^3HO\right)=0.85252$. Furthermore, $\Delta E_{H_2MO}\left(AO/HO\right)$ in Eq. (15.51) and $E_T\left(atom-atom,msp^3.AO\right)$ in Eq. (15.61) are both $-0.92918\ eV$ (Eq. (14.513)) per atom corresponding to $-3.71673\ eV$ in total. This is the maximum energy for a single bond and corresponds to methylene character as given in the Continuous-Chain Alkanes section.

The symbols of the functional groups of pyrrole are given in Table 15.267. The structure of pyrrole is shown in Figure 15.46B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of pyrrole are given in Tables 15.268, 15.269, and 15.270, respectively. The total energy of pyrrole given in Table 15.271 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.270 corresponding to functional-group composition of the molecule. The bond angle parameters of pyrrole determined using Eqs. (15.88-15.117) are given in Table 15.272. The color scale, translucent view of the charge-density of pyrrole comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.46A.

Figure 15.46. (A) Color scale, translucent view of the charge-density of pyrrole showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of pyrrole.

FURAN

Furan having the formula C_4H_4O comprises the conjugated alkene 1,3-butadiene that forms a cyclic structure by terminal-atom bonding to an oxygen atom. The two symmetrical carbon-to-oxygen bonds comprise the $C-O-C$ functional group. The 1,3-butadiene moiety comprises $C-C$, $C=C$, and CH functional groups. The CH, $C-C$, and $C=C$ groups are equivalent to the corresponding groups of pyrrole given in the corresponding section.

The $C-O-C$ functional group of furan is solved in a similar manner as that of the $C-N-C$ group of pyrrole. The solution of the $C-O-C$ functional group comprises the hybridization of the $2s$ and $2p$ AOs of each C to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ HOs and the oxygen atom to form a MO permits each participating hybridized orbital to decrease in radius and energy. Thus, the $C-O-C$-bond MO comprising a linear combination of two single bonds is solved in the same manner as a double bond with $n_1=2$ in Eqs. (15.51) and (15.61). The hybridization factor $c_2\left(arylC2sp^3HO\ to\ O\right)=0.79329$ (Eq. (15.169)) matches the double-bond character of the $C2sp^3$ HOs to the O atom, and C_2 and C_{2o} in Eqs. (15.51) and (15.61) become that of benzene given by Eq. (15.162), $C_2\left(benzeneC2sp^3HO\right)=0.85252$. Furthermore, $E_T\left(atom-atom,msp^3.AO\right)$ in Eq. (15.61) is $-0.92918\ eV$ (Eq. (14.513)) per atom corresponding to $-3.71673\ eV$ in total.

The symbols of the functional groups of furan are given in Table 15.273. The structure of furan is shown in Figure 15.47B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of furan are given in Tables 15.274, 15.275, and 15.276, respectively. The total energy of furan given in Table 15.277 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.276 corresponding to functional-group composition of the molecule. The bond angle parameters of furan determined using Eqs. (15.88-15.117) are given in Table 15.278. The color scale, translucent view of the charge-density of furan comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.47A.

Figure 15.47. (A) Color scale, translucent view of the charge-density of furan showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of furan.

THIOPHENE

Thiophene having the formula C_4H_4S comprises the conjugated alkene 1,3-butadiene that forms a cyclic structure by terminal-atom bonding to an oxygen atom. The two symmetrical carbon-to-sulfur bonds comprise the $C-S-C$ functional group. The 1,3-butadiene moiety comprises $C-C$, $C=C$, and CH functional groups. The CH, $C-C$, and $C=C$ groups are equivalent to the corresponding groups of pyrrole and furan given in the corresponding sections.

The $C-S-C$ functional group of thiophene is solved in a similar manner as that of the $C-N-C$ group of pyrrole and the $C-O-C$ group of furan. The solution of the $C-S-C$ functional group comprises the hybridization of the $2s$ and $2p$ AOs of each C to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between two $C2sp^3$ HOs and the sulfur atom to form a MO permits each participating hybridized orbital to decrease in radius and energy. Thus, the $C-S-C$-bond MO comprising a linear combination of two single bonds is solved in the same manner as a double bond with $n_1=2$ in Eqs. (15.51) and (15.61).

In thiophene, the energy of sulfur is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264). Thus, c_2 in Eq. (15.61) is $c_2\left(benzeneC2sp^3HO\right)=0.85252$ to match the double-bond character of the $C2sp^3$ HOs, and the energy matching condition is further determined by the C_2 parameter. Using the energy of S, $E\left(S\right)=-10.36001\ eV$ in Eq. (15.77) and the $C2sp^3$ HO energy of $E\left(C,2sp^3\right)=-15.76868\ eV$ (Eq. (15.18)) corresponding to $s=2$ in Eqs. (15.18-15.20), the hybridization factor C_2 of Eq. (15.61) for the $C-S-C$-bond MO is:

$$C_2\left(S3p\ to\ \text{aryl-type}\ C2sp^3HO\right)=\frac{E\left(S,3p\right)}{E\left(C,2sp^3\right)}=\frac{-10.36001\ eV}{-15.76868\ eV}=0.65700 \tag{15.172}$$

C_{1o} is also given by Eq. (15.172). Furthermore, $\Delta E_{H_2MO}\left(AO/HO\right)$ of the $C-S-C$-bond MO in Eq. (15.51) and $E_T\left(atom-atom,msp^3.AO\right)$ in Eq. (15.61) are both $-0.72457\ eV$ per atom corresponding to $-2.89830\ eV$ in total. The energy contribution equivalent to that of a methyl group (Eq. (14.151)) and that of the $C-S$-bond MO of thiols given in the corresponding section matches the energy of the sulfur atom to the $C2sp^3$ HOs.

The symbols of the functional groups of thiophene are given in Table 15.279. The structure of thiophene is shown in Figure 15.48B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of thiophene are given in Tables 15.280, 15.281, and 15.282, respectively. The total energy of thiophene given in Table 15.283 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.282 corresponding to functional-group composition of the molecule. The bond angle parameters of thiophene determined using Eqs. (15.88-15.117) are given in Table 15.284. The color scale, translucent view of the charge-density of thiophene comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.48A.

Figure 15.48. (A) Color scale, translucent view of the charge-density of thiophene showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of thiophene.

IMIDAZOLE

Imidazole having the formula $C_3H_4N_2$ comprises a conjugated system that is equivalent to pyrrole with one of the conjugated CH groups replaced by a nitrogen atom. The CH, NH, and $C=C$ groups are equivalent to the corresponding groups of pyrrole, furan, and thiophene where present. In addition, the nitrogen substitution creates a $C-N=C$ moiety comprising $C-N$ and $N=C$ functional groups. The $C-N$ bonding is the same as that of a tertiary amine except that the hybridization term c_2 in Eqs. (15.51) and (15.61) is that of the amino group of aniline, $c_2\left(arylC2sp^3HO\ to\ N\right)=0.84665$ (Eq. (15.171)). The hybridization factor provides double-bond character to match the group to the other orbitals of the molecule. $\Delta E_{H_2MO}\left(AO/HO\right)$ in Eq. (15.51) and $E_T\left(atom-atom,msp^3.AO\right)$ in Eq. (15.61) are both $-0.92918\ eV$ (Eq. (14.513)). This matches the energy of the group to that of the contiguous $N=C$ group wherein $\Delta E_{H_2MO}\left(AO/HO\right)$ in Eq. (15.51) and $E_T\left(atom-atom,msp^3.AO\right)$ in Eq. (15.61) are both $-0.92918\ eV$ (Eq. (14.513)) per atom of the double bond with aromatic character as in the case of the prior heterocyclic compounds. As in the prior cases of pyrrole, furan, and thiophene, $n_1=2$ and C_2 and C_{2o} are the same as $C_2\left(benzeneC2sp^3HO\right)=0.85252$ (Eq. (15.162)) in Eqs. (15.51) and (15.61). To match the energy of the nitrogen to the $C2sp^3$ HO, c_2 of the $N=C$-bond MO is also given by Eq. (15.171). These parameters also provide an energy match to the $C-N-C$ group.

As in the case of pyrrole, the $C-N-C$-bond MO comprising a linear combination of two single bonds is solved in the same manner as a double bond with $n_1=2$ in Eqs. (15.51) and (15.61). The hybridization factor $c_2\left(arylC2sp^3HO\ to\ N\right)=0.84665$ (Eq. (15.171)) matches the double-bond character of the $C2sp^3$ HOs to the N atom of the NH group, and C_2 and C_{2o} in Eqs. (15.51) and (15.61) become that of benzene given by Eq. (15.162), $C_2\left(benzeneC2sp^3HO\right)=0.85252$. Furthermore, $\Delta E_{H_2MO}\left(AO/HO\right)$ in Eq. (15.51) and $E_T\left(atom-atom,msp^3.AO\right)$ in Eq. (15.61) are both $-0.92918\ eV$ (Eq. (14.513)) per atom corresponding to $-3.71673\ eV$ in total.

The symbols of the functional groups of imidazole are given in Table 15.285. The structure of imidazole is shown in Figure 15.49B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of imidazole are given in Tables 15.286, 15.287, and 15.288, respectively. The total energy of imidazole given in Table 15.289 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.288 corresponding to functional-group composition of the molecule. The bond angle parameters of imidazole determined using Eqs. (15.88-15.117) are given in Table 15.290. The color scale, translucent view of the charge-density of imidazole, comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.49A.

Figure 15.49. (A) Color scale, translucent view of the charge-density of imidazole showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of imidizole.

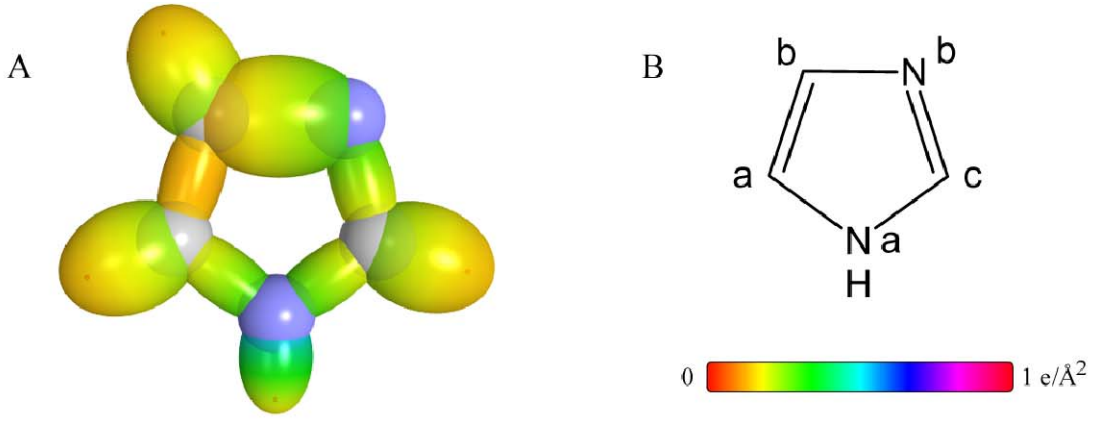

Table 15.285. The symbols of functional groups of imidazole.

Functional Group	Group Symbol
$C_a = C_b$ double bond	$C = C$
$N_b = C_c$ double bond	$N = C$
$C_b - N_b$	$C - N$
$C_a - N_a - C_c$	$C - N - C$
$N_a H$ group	NH
CH	CH

PYRIDINE

Pyridine has the formula C_5H_5N and comprises the benzene molecule with one CH group replaced by a nitrogen atom which gives rise to a $\overset{3e}{C=N}$ functional group. The aromatic $\overset{3e}{C=C}$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section with the aromaticity maintained by the electrons from nitrogen in the $\overset{3e}{C=N}$ group, which is also aromatic.

As in the case of the aromatic carbons of benzene, each pyridine $C2sp^3$ HO initially has four unpaired electrons. Each $C-H$ bond has two paired electrons with one donated from the H AO and the other from the $C2sp^3$ HO. In pyridine the three $N2p$ electrons are donated to the aromatic bond. Thus, as in the case of the $\overset{3e}{C=C}$ group, each $\overset{3e}{C=N}$ bond comprises a linear combination of a factor of 0.75 of four paired electrons (three electrons) from the $C2sp^3$ HO and the $N2p$ AO of the participating carbon and nitrogen atoms, respectively.

The solution of the $\overset{3e}{C=N}$ functional group comprises the hybridization of the $2s$ and $2p$ AOs of each C to form a single $2sp^3$ shell as an energy minimum, and the sharing of electrons between the $C2sp^3$ HO and the nitrogen atom to form a MO permits each participating hybridized orbital to decrease in radius and energy. The $\overset{3e}{C=N}$-bond MO is solved as a double bond with $n_1=2$ in Eqs. (15.51) and (15.166). The hybridization factor $c_2\left(C2sp^3 HO\ to\ N\right)=0.91140$ (Eq. (15.135)) matches the double-bond character of the $C2sp^3$ HO to the N atom, and C_2 and C_{2o} in Eqs. (15.51) and (15.166) are also given by Eq. (15.135) in order to match the nitrogen to the aromatic $C2sp^3$ HO such that $\Delta E_{H_2MO}\left(AO/HO\right)=0$ in Eq. (15.51). Furthermore, $E_T\left(atom-atom, msp^3.AO\right)$ of the $\overset{3e}{C=N}$-bond MO in Eq. (15.166) due to the charge donation from the C and N atoms to the MO is $-1.44915\ eV$ corresponding to an energy contribution from each atom that is equivalent to that of an independent methyl group, $-0.72457\ eV$ (Eq. (14.151)). The contributions are also the same as those for a primary amine group as given in the corresponding section. As in the case of benzene, the aromatic $E_T(Group)$ and $E_D(Group)$ are given by Eqs. (15.165) and (15.166), respectively, with $f_1=0.75$. The breakage of the CNC bonds results in three unpaired electrons on the N atom. Thus, the corresponding E_{mag} given by Eq. (15.69) was normalized for the two bonds per atom and for $f_1=0.75$ and was subtracted from the total energy of the $\overset{3e}{C=N}$-bond MO in Eq. (15.166). The pyridine vibrational energies are similar to those of benzene [63]; thus, the value for benzene was used.

The symbols of the functional groups of pyridine are given in Table 15.291. The corresponding designation of the structure is shown in Figure 15.50B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of pyridine are given in Tables 15.292, 15.293, and 15.294, respectively. The total energy of pyridine given in Table 15.295 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.294 corresponding to functional-group composition of the molecule. The bond angle parameters of pyridine determined using Eqs. (15.88-15.117) are given in Table 15.296. The color scale, translucent view of the charge-density of pyridine comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.50A.

Figure 15.50. (A) Color scale, translucent view of the charge-density of pyridine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of pyridine.

PYRIMIDINE

Pyrimidine has the formula $C_4H_4N_2$ and comprises the pyridine molecule with one additional CH group replaced by a nitrogen atom, which gives rise to a second $C^{3e}{=}N$ functional group that is equivalent to that of pyridine given in the corresponding section. The aromatic $C^{3e}{=}C$ and $C-H$ functional groups are also equivalent to those of pyridine and benzene given in the Aromatic and Heterocyclic Compounds section with the aromaticity maintained by the electrons from nitrogen in the $C^{3e}{=}N$ group which is also aromatic.

The symbols of the functional groups of pyrimidine are given in Table 15.297. The corresponding designation of the structure is shown in Figure 15.51B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of pyrimidine are given in Tables 15.298, 15.299, and 15.300, respectively. The total energy of pyrimidine given in Table 15.301 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.300 corresponding to functional-group composition of the molecule. The bond angle parameters of pyrimidine determined using Eqs. (15.88-15.117) are given in Table 15.302. The color scale, translucent view of the charge-density of pyrimidine comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.51A.

Figure 15.51. (A) Color scale, translucent view of the charge-density of pyrimidine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of pyrimidine.

PYRAZINE

Pyrazine has the formula $C_4H_4N_2$ and comprises the pyrimidine molecule with para rather than ortho aromatic nitrogen atoms. The $C\overset{3e}{=}N$ functional group is equivalent to that of pyrimidine and pyridine given in the corresponding sections. The aromatic $C\overset{3e}{=}C$ and $C-H$ functional groups are also equivalent to those of pyrimidine, pyridine, and benzene given in the Aromatic and Heterocyclic Compounds section with the aromaticity maintained by the electrons from nitrogen in the $C\overset{3e}{=}N$ group, which is also aromatic.

The symbols of the functional groups of pyrazine are given in Table 15.303. The corresponding designation of the structure is shown in Figure 15.52B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of pyrazine are given in Tables 15.304, 15.305, and 15.306, respectively. The total energy of pyrazine given in Table 15.307 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.306 corresponding to functional-group composition of the molecule. The bond angle parameters of pyrazine determined using Eqs. (15.88-15.117) are given in Table 15.308. The color scale, translucent view of the charge-density of pyrazine comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.52A.

Figure 15.52. (A) Color scale, translucent view of the charge-density of pyrazine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of pyrazine.

QUINOLINE

Quinoline has the formula C_9H_7N and comprises the naphthalene molecule with one CH group replaced by a nitrogen atom which gives rise to a $C\overset{3e}{=}N$ functional group. The aromatic $C\overset{3e}{=}C$ and $C-H$ functional groups are equivalent to those of naphthalene given in the corresponding section with the aromaticity maintained by the electrons from nitrogen in the $C\overset{3e}{=}N$ group, which is also aromatic. The $C-C$ functional group is also equivalent to that of naphthalene. The bonding in quinoline can be further considered as a linear combination of the naphthalene and pyridine groups wherein the $C\overset{3e}{=}N$ group is equivalent to that of pyridine, pyrimidine, and pyrazine as given in the corresponding sections.

The symbols of the functional groups of quinoline are given in Table 15.309. The corresponding designation of the structure is shown in Figure 15.53B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of quinoline are given in Tables 15.310, 15.311, and 15.312, respectively. The total energy of quinoline given in Table 15.313 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.312 corresponding to functional-group composition of the molecule. The bond angle parameters of quinoline determined using Eqs. (15.88-15.117) are given in Table 15.314. The color scale, translucent view of the charge-density of quinoline comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.53A.

Figure 15.53. (A) Color scale, translucent view of the charge-density of quinoline showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of quinoline.

ISOQUINOLINE

Isoquinoline has the formula C_9H_7N and comprises the naphthalene molecule with one CH group replaced by a nitrogen atom which gives rise to a $C\overset{3e}{=}N$ functional group. Isoquinoline is also equivalent to quinoline with the nitrogen in the meta rather than the ortho position relative to the benzene ring of the molecule. The aromatic $C\overset{3e}{=}C$ and $C-H$ functional groups are equivalent to those of naphthalene given in the corresponding section with the aromaticity maintained by the electrons from nitrogen in the $C\overset{3e}{=}N$ group which is also aromatic. The $C-C$ functional group is also equivalent to that of naphthalene. The bonding in isoquinoline can be further considered as a linear combination of the naphthalene and pyridine groups wherein the $C\overset{3e}{=}N$ group is equivalent to that of pyridine, pyrimidine, pyrazine, and quinoline as given in the corresponding sections.

The symbols of the functional groups of isoquinoline are given in Table 15.315. The corresponding designation of the structure is shown in Figure 15.54B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of isoquinoline are given in Tables 15.316, 15.317, and 15.318, respectively. The total energy of isoquinoline given in Table 15.319 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.318 corresponding to functional-group composition of the molecule. The bond angle parameters of isoquinoline determined using Eqs. (15.88-15.117) are given in Table 15.320. The color scale, translucent view of the charge-density of isoquinoline comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.54A.

Figure 15.54. (A) Color scale, translucent view of the charge-density of isoquinoline showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of isoquinoline.

INDOLE

Indole having the formula C_8H_7N comprises a phenyl moiety with a conjugated five-membered ring which comprises pyrrole except that one of the double bonds is part of the aromatic ring. The structure is shown in Figure 15.55B. The aromatic $C\overset{3e}{=}C$ and $C-H$ functional groups of the phenyl moiety are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The CH, NH, and $C_d=C_e$ groups of the pyrrole-type ring are equivalent to the corresponding groups of pyrrole, furan, and thiophene where present as given in the corresponding sections. The C_b-C_d single bond of aryl carbon to the $C_d=C_e$ bond is also a functional group. This group is equivalent to the $C-C(O)$ group of benzoic acids with regard to $\Delta E_{H_2MO}\left(AO/HO\right)$ in Eq. (15.51) and $E_T\left(atom-atom,msp^3.AO\right)$ in Eq. (15.61) both being $-1.29147\,eV$. This energy is a linear combination of $\frac{-1.13379\,eV}{2}$, $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-H$ group that the C_b-C_d and $C-C(O)$ groups replace, and that of an independent $C2sp^3$ HO, $-0.72457\,eV$ (Eq. (14.151)). However, as in the case of pyrrole, the indole hybridization term c_2 is the aromatic $c_2\left(benzeneC2sp^3HO\right)=0.85252$ to match the aryl $C2sp^3$ HO, and the energy terms corresponding to oscillation in the transition state correspond to indole.

As in the case of pyrrole, the $C-N-C$-bond MO comprising a linear combination of two single bonds is solved in the same manner as a double bond with $n_1=2$ in Eqs. (15.51) and (15.61). The hybridization factor $c_2\left(arylC2sp^3HO\ to\ N\right)=0.84665$ (Eq. (15.171)) matches the aromatic character of the $C2sp^3$ HOs to the N atom of the NH group, and C_2 and C_{2o} in Eqs. (15.51) and (15.61) become that of benzene given by Eq. (15.162), $C_2\left(benzeneC2sp^3HO\right)=0.85252$. Furthermore, $\Delta E_{H_2MO}\left(AO/HO\right)$ in Eq. (15.51) and $E_T\left(atom-atom,msp^3.AO\right)$ in Eq. (15.61) are both $-2.42526\,eV$ which is a linear combination of $\frac{-1.13379\,eV}{2}$, $E_T\left(atom-atom,msp^3.AO\right)$ of the $C-H$ group that the C_c-N bond replaces, and $-1.85836\,eV$ (Eq. (14.513)) which is equivalent to the corresponding component of the $C-N-C$-bond of pyrrole.

The symbols of the functional groups of indole are given in Table 15.321. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of indole are given in Tables 15.322, 15.323, and 15.324, respectively. The total energy of indole given in Table 15.325 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.324 corresponding to functional-group composition of the molecule. The bond angle parameters of indole determined using Eqs. (15.88-15.117) are given in Table 15.326. The color scale, translucent view of the charge-density of indole comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.55A.

Figure 15.55. (A) Color scale, translucent view of the charge-density of indole showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and atom designation of indole.

ADENINE

Adenine having the formula $C_5H_5N_5$ comprises a pyrimidine moiety with an aniline-type moiety and a conjugated five-membered ring, which comprises imidazole except that one of the double bonds is part of the aromatic ring. The structure is shown in Figure 15.56B. The aromatic $C\overset{3e}{=}C$, $C-H$, and $C\overset{3e}{=}N$ functional groups of the pyrimidine moiety are equivalent to those of pyrimidine as given in the corresponding section. The CH, NH, C_d-N_e, and $N_e=C_e$ groups of the imidazole-type ring are equivalent to the corresponding groups of imidazole as given in the corresponding section. The $C-N-C$ functional group of the imidazole-type ring is equivalent to the corresponding group of indole having the same structure with the $C-N-C$ group bonding to aryl and alkenyl groups. The NH_2 and C_a-N_a functional groups of the aniline-type moiety are equivalent to those of aniline as given in the corresponding section except that $\Delta E_{H_2MO}\left(AO/HO\right)$ of the C_a-N_a group is equal to twice $E_T\left(atom-atom,msp^3.AO\right)$, and to meet the equipotential condition of the union of the $C-N$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor c_2 of Eq. (15.60) for the $C-N$-bond MO given by Eqs. (15.77), (15.79), and (15.162) is:

$$c_2\left(arylC2sp^3HO\ to\ N\right)=\frac{E\left(N\right)}{E\left(C,2sp^3\right)}c_2\left(arylC2sp^3HO\right)=\frac{-14.53414\ eV}{-15.95955\ eV}\left(0.85252\right)=0.77638 \tag{15.173}$$

The symbols of the functional groups of adenine are given in Table 15.327. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of adenine are given in Tables 15.328, 15.329, and 15.330, respectively. The total energy of adenine given in Table 15.331 was calculated as the sum over the integer multiple of each $E_D\left(Group\right)$ of Table 15.330 corresponding to functional-group composition of the molecule. The bond angle parameters of adenine determined using Eqs. (15.88-15.117) are given in Table 15.332. The color scale, charge-density of adenine comprising atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.56A.

Figure 15.56. (A) Color scale, charge-density of adenine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure and atomic designation of adenine.

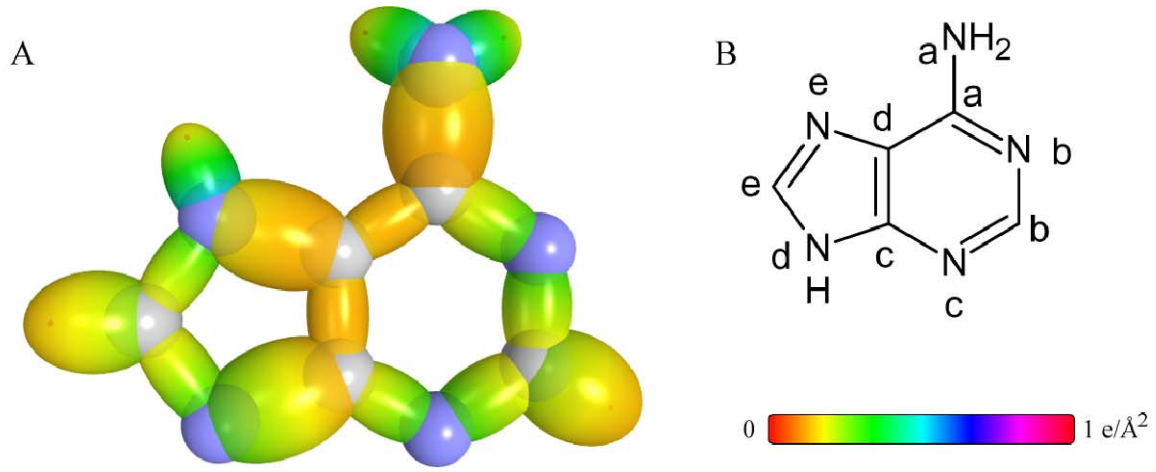

Table 15.327. The symbols of functional groups of adenine.

Functional Group	Group Symbol
CC (aromatic bond)	$C \overset{3e}{=} C$
CH (aromatic)	CH (i)
$C_{b,c} \overset{3e}{=} N_c \qquad C_{a,b} \overset{3e}{=} N_b$	$C \overset{3e}{=} N$
$C_a - N_a$	$C - N$ (a)
NH_2 group	NH_2
$N_e = C_e$ double bond	$N = C$
$C_d - N_e$	$C - N$ (b)
$N_d H$ group	NH
CH	CH (ii)
$C_c - N_d - C_e$	$C - N - C$

THYMINE

Thymine having the formula $C_5H_6N_2O_2$ is a pyrimidine with carbonyl substitutions at positions C_a and C_b and a methyl substitution at position C_d further comprising a vinyl group as shown in Figure 15.57B. Each $C=O$, adjacent $C-N$, and NH functional group is equivalent to the corresponding group of alkyl amides. The methyl-vinyl moiety is equivalent to the CH_3, $-C(C)=C$, CH, and $C=C$ functional groups of alkenes. Thymine further comprises N_bH and $C_b-N_c-C_c$ groups that are equivalent to the corresponding groups of imidazole as given in the corresponding section. The C_a-C_d bond comprises another functional group that is equivalent to the C_a-C_d group of guanine.

The symbols of the functional groups of thymine are given in Table 15.333. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of thymine are given in Tables 15.334, 15.335, and 15.336, respectively. The total energy of thymine given in Table 15.337 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.336 corresponding to functional-group composition of the molecule. The bond angle parameters of thymine determined using Eqs. (15.88-15.117) are given in Table 15.338. The color scale, charge-density of thymine comprising atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.57A.

Figure 15.57. (A) Color scale, charge-density of thymine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure and atom designation of thyamine.

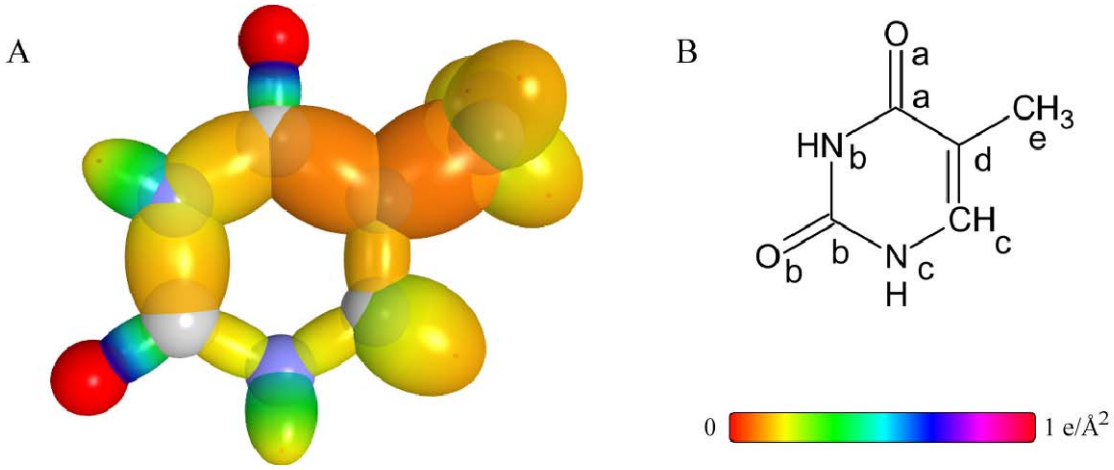

Table 15.333. The symbols of functional groups of thymine.

Functional Group	Group Symbol
$C_a=O$ $C_b=O$ (alkyl amide)	$C=O$

GUANINE

Guanine having the formula $C_5H_5N_5O$ is a purine with a carbonyl substitution at position C_a, and a primary amine moiety is at position C_b as shown in Figure 15.58B. The carbonyl functional group is equivalent to that of alkyl amides and the NH_2 and C_b-N_a functional groups of the primary amine moiety are equivalent to the NH_2 and C_a-N_a functional groups of adenine. Guanine further comprises an imidazole moiety wherein the CH, N_dH, $C_d=C_c$, C_d-N_e, $N_e=C_e$, and $C_c-N_d-C_e$ groups of the imidazole-type ring are equivalent to the corresponding groups of imidazole as given in the corresponding section. The six-membered ring also comprises the groups $C_a-N_b-C_b$, N_bH, $N_c=C_c$, and C_c-N_d that are equivalent to the corresponding imidazole and adenine functional groups. The C_a-C_d bond comprises another functional group that is the C_{60}-single-bond functional group except that $E_T\left(atom-atom, msp^3.AO\right)=0$ in order to match the energies of the single and double-bonded moieties within the molecule.

The symbols of the functional groups of guanine are given in Table 15.339. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of guanine are given in Tables 15.340, 15.341, and 15.342, respectively. The total energy of guanine given in Table 15.343 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.342 corresponding to functional-group composition of the molecule. The bond angle parameters of guanine determined using Eqs. (15.88-15.117) are given in Table 15.344. The color scale, charge-density of guanine comprising atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.58A.

Figure 15.58. (A) Color scale, charge-density of guanine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure and atomic designation of guanine.

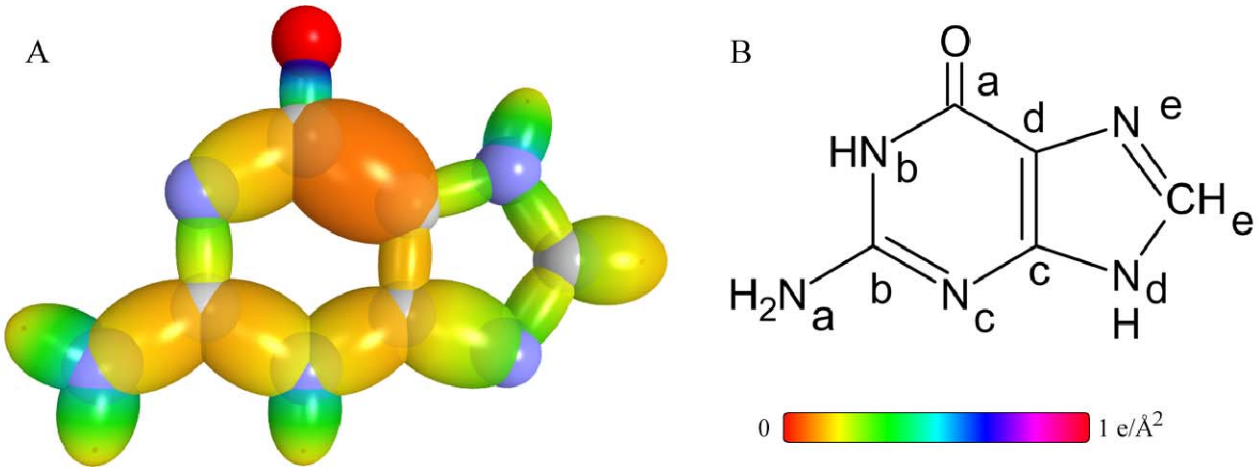

Table 15.339. The symbols of functional groups of guanine.

Functional Group	Group Symbol
$C_a = O$ (alkyl amide)	$C = O$

CYTOSINE

Cytosine having the formula $C_4H_5N_3O$ is a pyrimidine with a carbonyl substitution at position C_b, and a primary amine moiety is at position C_a as shown in Figure 15.59B. The carbonyl and adjacent $C_b - N_b$ functional groups are equivalent to the corresponding groups of alkyl amides. The NH_2 and $C_a - N_a$ functional groups of the primary amine moiety are equivalent to the NH_2 and $C_a - N_a$ functional groups of adenine. The vinyl moiety, $HC_c = C_dH$, comprises $C = C$ and CH functional groups that are equivalent to the corresponding alkene groups. Cytosine further comprises $N_b = C_a$, N_cH, and $C_b - N_c - C_c$ groups that are equivalent to the corresponding groups of imidazole as given in the corresponding section. The $C_a - C_d$ bond comprises another functional group that is equivalent to the $C_a - C_d$ group of guanine and thymine except that $E_T\left(atom - atom, msp^3.AO\right)$ is equivalent to the contribution of a $C2sp^3$ HO of an alkane, $-0.92918\ eV$ (Eq. (14.513)), in order to match the energies of the single and double-bonded moieties within the molecule.

The symbols of the functional groups of cytosine are given in Table 15.345. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of cytosine are given in Tables 15.346, 15.347, and 15.348, respectively. The total energy of cytosine given in Table 15.349 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.348 corresponding to functional-group composition of the molecule. The bond angle parameters of cytosine determined using Eqs. (15.88-15.117) are given in Table 15.350. The color scale, charge-density of cytosine comprising atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.59A.

Figure 15.59. (A) Color scale, charge-density of cytosine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure and atomic designation of cytosine.

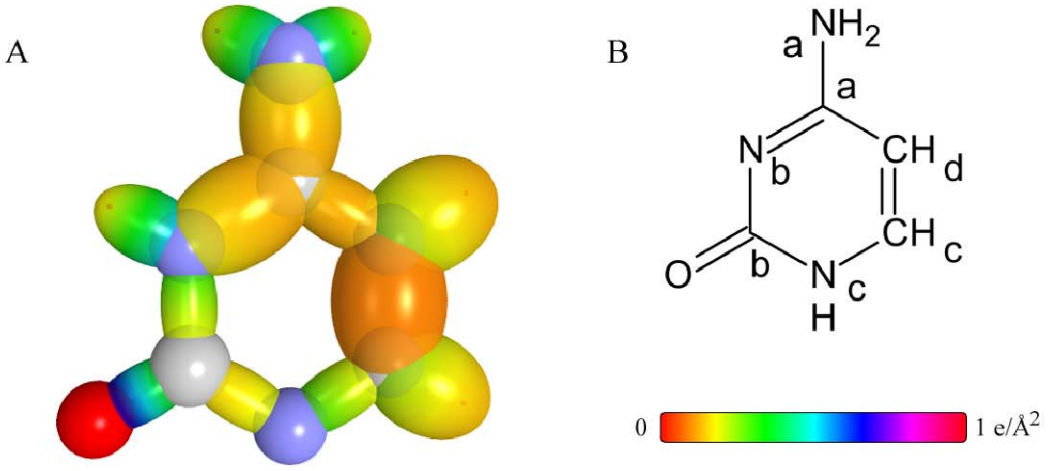

Table 15.345. The symbols of functional groups of cytosine.

Functional Group	Group Symbol
$C_a - N_a$	$C - N$ (a)
NH_2 group	NH_2
$N_b = C_a$ double bond	$N = C$
$C_b = O$ (alkyl amide)	$C = O$
$C_b - N_b$ amide	$C - N$ (b)
$C_c = C_d$ double bond	$C = C$
$C_cH \quad C_dH$	CH
$C_a - C_d$	$C - C$
$C_b - N_c - C_c$	$C - N - C$
N_cH group	NH

ALKYL PHOSPHINES ($\left(C_nH_{2n+1}\right)_3P,\ n=1,2,3,4,5...\infty$)

The alkyl phosphines, $\left(C_nH_{2n+1}\right)_3P$, comprise a $P-C$ functional group. The alkyl portion of the alkyl phosphine may comprise at least two terminal methyl groups (CH_3) at each end of each chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($\left(CH_3\right)_2CH$) and t-butyl ($\left(CH_3\right)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl phosphines are equivalent to those in branched-chain alkanes. The $P-C$ group may further join the $P3sp^3$ HO to an aryl HO.

As in the case of carbon, the bonding in the phosphorous atom involves sp^3 hybridized orbitals formed, in this case, from the $3p$ and $3s$ electrons of the outer shells with five $P3sp^3$ HOs rather than four $C2sp^3$ HOs. The $P-C$ bond forms between $P3sp^3$ and $C2sp^3$ HOs to yield phosphines. The semimajor axis a of the $P-C$ functional group is solved using Eq. (15.51). Using the semimajor axis and the relationships between the prolate spheroidal axes, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in Organic Molecular Functional Groups and Molecules section.

The energy of phosphorous is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264). A minimum energy is achieved while matching the potential, kinetic, and orbital energy relationships given in the Hydroxyl Radical (OH) section with hybridization of the phosphorous atom such that in Eqs. (15.51) and (15.61), the sum of the energies of the H_2-type ellipsoidal MOs is matched to that of the $P3sp^3$ shell as in the case of the corresponding carbon and silicon molecules.

The P electron configuration is $[Ne]3s^23p^3$ corresponding to the ground state ${}^4S_{3/2}$, and the $3sp^3$ hybridized orbital arrangement after Eq. (13.422) is:

$$\begin{array}{cccc} & 3\text{sp}^3 \text{ state} & & \\ \uparrow\downarrow & \uparrow & \uparrow & \uparrow \\ \hline 0,0 & 1,\text{-}1 & 1,0 & 1,1 \end{array} \tag{15.174}$$

where the quantum numbers (ℓ, m_ℓ) are below each electron. The total energy of the state is given by the sum over the five electrons. The sum $E_T\left(P,3sp^3\right)$ of experimental energies [38] of P, P^+, P^{2+}, P^{3+}, and P^{4+} is:

$$\begin{aligned} E_T\left(P,3sp^3\right) &= 65.0251\ eV + 51.4439\ eV + 30.2027\ eV + 19.7695\ eV + 10.48669\ eV \\ &= 176.92789\ eV \end{aligned} \tag{15.175}$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius r_{3sp^3} of the $P3sp^3$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$r_{3sp^3} = \sum_{n=10}^{14} \frac{(Z-n)e^2}{8\pi\varepsilon_0\left(e176.92789\ eV\right)} = \frac{15e^2}{8\pi\varepsilon_0\left(e176.92789\ eV\right)} = 1.15350a_0 \tag{15.176}$$

where $Z=15$ for phosphorous. Using Eq. (15.14), the Coulombic energy $E_{Coulomb}\left(P,3sp^3\right)$ of the outer electron of the $P3sp^3$ shell is:

$$E_{Coulomb}\left(P,3sp^3\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{3sp^3}} = \frac{-e^2}{8\pi\varepsilon_0 1.15350a_0} = -11.79519\ eV \tag{15.177}$$

During hybridization, the spin-paired $3s$ electrons are promoted to the $P3sp^3$ shell as paired electrons at the radius r_{3sp^3} of the $P3sp^3$ shell. The energy for the promotion is the difference in the magnetic energy given by Eq. (15.15) at the initial radius of the $3s$ electrons and the final radius of the $P3sp^3$ electrons. From Eq. (10.255) with $Z=15$, the radius r_{12} of $P3s$ shell is

$$r_{12} = 1.09443a_0 \tag{15.178}$$

Using Eqs. (15.15) and (15.178), the unpairing energy is:

$$E(magnetic) = \frac{2\pi\mu_0 e^2\hbar^2}{m_e^2}\left(\frac{1}{\left(r_{12}\right)^3} - \frac{1}{\left(r_{3sp^3}\right)^3}\right) = 8\pi\mu_o\mu_B^2\left(\frac{1}{\left(1.09443a_0\right)^3} - \frac{1}{\left(1.15350a_0\right)^3}\right) = 0.01273\ eV \tag{15.179}$$

Using Eqs. (15.177) and (15.179), the energy $E\left(P,3sp^3\right)$ of the outer electron of the $P3sp^3$ shell is:

$$E\left(P,3sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{3sp^3}}+\frac{2\pi\mu_0 e^2\hbar^2}{m_e^2}\left(\frac{1}{\left(r_{12}\right)^3}-\frac{1}{\left(r_{3sp^3}\right)^3}\right)=-11.79519\ eV+0.01273\ eV=-11.78246\ eV \tag{15.180}$$

For the $P-C$ functional group, hybridization of the $2s$ and $2p$ AOs of each C and the $3s$ and $3p$ AOs of each P to form single $2sp^3$ and $3sp^3$ shells, respectively, forms an energy minimum, and the sharing of electrons between the $C2sp^3$ and $P3sp^3$ HOs to form a MO permits each participating orbital to decrease in radius and energy. In branched-chain alkyl phosphines, the energy of phosphorous is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264). Thus, c_2 in Eq. (15.61) is one, and the energy matching condition is determined by the C_2 parameter. Then, the $C2sp^3$ HO has an energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)), and the $P3sp^3$ HO has an energy of $E\left(P,3sp^3\right)=-11.78246\ eV$ (Eq. (15.180)). To meet the equipotential condition of the union of the $P-C$ H_2-type-ellipsoidal-MO with these orbitals, the hybridization factor C_2 of Eq. (15.61) for the $P-C$-bond MO given by Eqs. (15.77), (15.79), and (13.430) is:

$$C_2\left(C2sp^3HO\ to\ P3sp^3HO\right)=\frac{E\left(P,3sp^3\right)}{E\left(C,2sp^3\right)}c_2\left(C2sp^3HO\right)=\frac{-11.78246\ eV}{-14.63489\ eV}\left(0.91771\right)=0.73885 \tag{15.181}$$

The energy of the $P-C$-bond MO is the sum of the component energies of the H_2-type ellipsoidal MO given in Eq. (15.51) with $E\left(AO/HO\right)=E\left(P,3sp^3\right)$ given by Eq. (15.180), and $E_T\left(atom-atom,msp^3.AO\right)$ is one half $-0.72457\ eV$ given by Eq. (14.151) in order to match the energies of the carbon and phosphorous HOs.

The symbols of the functional groups of branched-chain alkyl phosphines are given in Table 15.351. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl phosphines are given in Tables 15.352, 15.353, and 15.354, respectively. The total energy of each alkyl phosphine given in Table 15.355 was calculated as the sum over the integer multiple of each $E_D\left(Group\right)$ of Table 15.354 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl phosphines determined using Eqs. (15.88-15.117) are given in Table 15.356. The color scale, charge-density of exemplary alkyl phosphine, triphenylphosphine, comprising atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.60.

Figure 15.60. Color scale, charge-density of triphenylphosphine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (A) Top view. (B) Side view.

ALKYL PHOSPHITES ($\left(C_nH_{2n+1}O\right)_3P,\ \ n=1,2,3,4,5...\infty$)

The alkyl phosphites, $\left(C_nH_{2n+1}O\right)_3P$, comprise $P-O$ and $C-O$ functional groups. The alkyl portion of the alkyl phosphite may comprise at least two terminal methyl groups (CH_3) at each end of each chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($\left(CH_3\right)_2CH$) and t-butyl ($\left(CH_3\right)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl phosphites are equivalent to those in branched-chain alkanes.

The ether portion comprises two types of $C-O$ functional groups, one for methyl or t-butyl groups corresponding to the C, and the other for general alkyl groups that are equivalent to those in the Ethers section. The $P-O$ bond forms between the $P3sp^3$ HO and an $O2p$ AO to yield phosphites. The semimajor axis a of the $P-O$ functional group is solved using Eq. (15.51). Using the semimajor axis and the relationships between the prolate spheroidal axes, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in Organic Molecular Functional Groups and Molecules section.

For the $P-O$ functional group, hybridization the $3s$ and $3p$ AOs of each to form a single $3sp^3$ shell forms an energy minimum, and the sharing of electrons between the $O2p$ AOs and $P3sp^3$ HOs to form a MO permits each participating orbital to decrease in radius and energy. The O AO has an energy of $E\left(O\right)=-13.61805\ eV$, and the $P3sp^3$ HO has an energy of $E\left(P,3sp^3\right)=-11.78246\ eV$ (Eq. (15.180)). In branched-chain alkyl phosphites, the energy matching condition is determined by the c_2 and C_2 parameters of Eq. (15.51) given by Eqs. (15.77), (15.79), and (13.430).

$$c_2\ and\ C_2\left(O2pAO\ to\ P3sp^3HO\right)=\frac{E\left(P,3sp^3\right)}{E\left(O,2p\right)}c_2\left(C2sp^3HO\right)=\frac{-11.78246\ eV}{-13.61805\ eV}\left(0.91771\right)=0.79401 \tag{15.182}$$

The energy of the $P-O$-bond MO is the sum of the component energies of the H_2-type ellipsoidal MO given in Eq. (15.51) with $E\left(AO/HO\right)$ being $E\left(P,3sp^3\right)$ given by Eq. (23.180), and $E_T\left(atom-atom,msp^3.AO\right)$ is equivalent to that of single bond, $-1.44914\ eV$, given by twice Eq. (14.151) in order to match the energies of the oxygen AO with the phosphorous and carbon HOs.

The symbols of the functional groups of branched-chain alkyl phosphites are given in Table 15.357. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl phosphites are given in Tables 15.358, 15.359, and 15.360, respectively. The total energy of each alkyl phosphite given in Table 15.361 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.360 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl phosphites determined using Eqs. (15.88-15.117) are given in Table 15.362. The color scale, charge-density of exemplary alkyl phosphite, tri-isopropyl phosphite, comprising atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.61.

Figure 15.61. Color scale, charge-density of tri-isopropyl phosphite showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei.

ALKYL PHOSPHINE OXIDES ($\left(C_nH_{2n+1}\right)_3 P=O,\ n=1,2,3,4,5...\infty$)

The alkyl phosphine oxides, $\left(C_nH_{2n+1}\right)_3 P=O$, comprise $P-C$ and $P=O$ functional groups. The alkyl portion of the alkyl phosphine oxide may comprise at least two terminal methyl groups (CH_3) at each end of each chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($\left(CH_3\right)_2 CH$) and t-butyl ($\left(CH_3\right)_3 C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl phosphine oxides are equivalent to those in branched-chain alkanes.

The $P-C$ functional group is equivalent to that of alkyl phosphines. The $P=O$ bond forms between the $P3sp^3$ HO and an $O2p$ AO to yield phosphine oxides. The semimajor axis a of the $P=O$ functional group is solved using Eq. (15.51). Using the semimajor axis and the relationships between the prolate spheroidal axes, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in Organic Molecular Functional Groups and Molecules section.

For the $P=O$ functional group, hybridization the $3s$ and $3p$ AOs of each P to form a single $3sp^3$ shells forms an energy minimum, and the sharing of electrons between the $O2p$ AOs and $P3sp^3$ HOs to form a MO permits each participating orbital to decrease in radius and energy. In branched-chain alkyl phosphine oxides, the energy of phosphorous is less than the Coulombic energy between the electron and proton of H given by Eq. (1.264). The energy matching condition is determined by the c_2 parameter given by Eq. (15.182). The energy of the $P=O$-bond MO is the sum of the component energies of the H_2-type ellipsoidal MO given in Eq. (15.51) with $E\left(AO/HO\right)$ being twice $E\left(P,3sp^3\right)$ given by Eq. (15.180) corresponding to the double bond, and $E_T\left(atom-atom,msp^3.AO\right)$ is equivalent to that of an alkene double bond, $-2.26758\,eV$, given by Eq. (14.247) in order to match the energies of the carbon and phosphorous HOs and the oxygen AO.

The symbols of the functional groups of branched-chain alkyl phosphine oxides are given in Table 15.363. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl phosphine oxides are given in Tables 15.364, 15.365, and 15.366, respectively. The total energy of each alkyl phosphine oxide given in Table 15.367 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 15.366 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl phosphine oxides determined using Eqs. (15.88-15.117) are given in Table 15.368. The color scale, charge-density of exemplary alkyl phosphine oxide, trimethylphosphine oxide, comprising atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.62.

Figure 15.62. Color scale, charge-density of trimethylphosphine oxide showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (A) Top view. (B) Side view.

ALKYL PHOSPHATES ($\left(C_nH_{2n+1}O\right)_3P=O,\ n=1,2,3,4,5...\infty$)

The alkyl phosphates, $\left(C_nH_{2n+1}O\right)_3P=O$, comprise $P=O$, $P-O$, and $C-O$ functional groups. The $P=O$ functional group is equivalent to that of alkyl phosphine oxides. The $P-O$ and $C-O$ functional groups are equivalent to those of alkyl phosphites. The alkyl portion of the alkyl phosphate may comprise at least two terminal methyl groups (CH_3) at each end of each chain, and may comprise methylene (CH_2), and methylyne (CH) functional groups as well as C bound by carbon-carbon single bonds. The methyl and methylene functional groups are equivalent to those of straight-chain alkanes. Six types of $C-C$ bonds can be identified. The n-alkane $C-C$ bond is the same as that of straight-chain alkanes. In addition, the $C-C$ bonds within isopropyl ($\left(CH_3\right)_2CH$) and t-butyl ($\left(CH_3\right)_3C$) groups and the isopropyl to isopropyl, isopropyl to t-butyl, and t-butyl to t-butyl $C-C$ bonds comprise functional groups. The branched-chain-alkane groups in alkyl phosphates are equivalent to those in branched-chain alkanes.

The symbols of the functional groups of branched-chain alkyl phosphates are given in Table 15.369. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of alkyl phosphates are given in Tables 15.370, 15.371, and 15.372, respectively. The total energy of each alkyl phosphate given in Table 15.373 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 15.372 corresponding to functional-group composition of the molecule. The bond angle parameters of alkyl phosphates determined using Eqs. (15.88-15.117) are given in Table 15.374. The color scale, charge-density of exemplary alkyl phosphate, tri-isopropyl phosphate, comprising of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.63.

Figure 15.63. Color scale, charge-density of tri-isopropyl phosphate showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei.

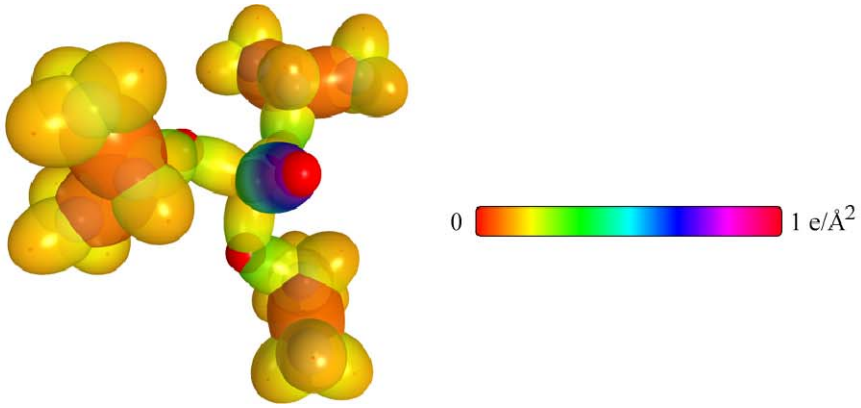

Table 15.369. The symbols of functional groups of alkyl phosphates.

ORGANIC AND RELATED IONS (RCO_2^-, $ROSO_3^-$, NO_3^-, $(RO)_2PO_2^-$, $(RO)_3SiO^-$, $(R)_2Si(O^-)_2$, RNH_3^+, $R_2NH_2^+$)

Proteins comprising amino acids with amino and carboxylic acid groups are charged at physiological pH. Deoxyribonucleic acid (DNA), the genetic material of living organisms also comprises negatively charged phosphate groups. Thus, the bonding of organic ions is considered next. The molecular ions also comprise functional groups that have an additional electron or are deficient by an electron in the cases of monovalent molecular anions and cations, respectively. The molecular chemical bond typically comprises an even integer number of paired electrons, but with an excess of deficiency, the bonding may involve an odd number of electrons, and the electrons may be distributed over multiple bonds, solved as a linear combination of standard bonds. As given in the Benzene Molecule section and other sections on aromatic molecules such as naphthalene, toluene, chlorobenzene, phenol, aniline, nitrobenzene, benzoic acid, pyridine, pyrimidine, pyrazine, quinoline, isoquinoline, indole, and adenine, the paired electrons of MOs may be distributed over a linear combination of bonds such that the bonding between two atoms involves less than an integer multiple of two electrons. Specifically, the results of the derivation of the parameters of the benzene molecule given in the Benzene Molecule (C_6H_6) section was generalized to any aromatic functional group of aromatic and heterocyclic compounds in the Aromatic and Heterocyclic Compounds section. Ethylene serves as a basis element for the $C\overset{3e}{=}C$ bonding of the aromatic bond wherein each of the $C\overset{3e}{=}C$ aromatic bonds comprises $(0.75)(4)=3$ electrons according to Eq. (15.161). Thus, in these aromatic cases, three electrons can be assigned to a given bond between two atoms wherein the electrons of the linear combination of bonded atoms are paired and comprise an integer multiple of two.

In graphite, the minimum energy structure with equivalent carbon atoms wherein each carbon forms bonds with three other such carbons requires a redistribution of charge within an aromatic system of bonds. Considering that each carbon contributes four bonding electrons, the sum of electrons of a vertex-atom group is four from the vertex atom plus two from each of the two atoms bonded to the vertex atom where the latter also contribute two each to the juxtaposed group. These eight electrons are distributed equivalently over the three bonds of the group such that the electron number assignable to each bond is $\frac{8}{3}$. Thus, the $C\overset{8/3e}{=}C$ functional group of graphite comprises the aromatic bond with the exception that the electron-number per bond is $\frac{8}{3}$.

As given in the Bridging Bonds of Boranes section and the Bridging Bonds of Organoaluminum Hydrides section, other examples of electron deficient bonding involving two paired electrons centered on three atoms are *three-center bonds* as opposed to the typical single bond, a *two-center bond*. The $B2sp^3$ HOs comprise four orbitals containing three electrons as given by Eq. (23.1) that can form three-center as well as two-center bonds. The designation for a three-center bond involving two $B2sp^3$ HOs and a $H1s$ AO is $B-H-B$, and the designation for a three-center bond involving three $B2sp^3$ HOs is $B-B-B$. In the aluminum case, each $Al-H-Al$-bond MO and $Al-C-Al$-bond MO comprises the corresponding single bond and forms with further sharing of electrons between each $Al3sp^3$ HO and each $H1s$ AO and $C2sp^3$ HO, respectively. Thus, the geometrical and energy parameters of the three-center bond are equivalent to those of the corresponding two-center bonds except that the bond energy is increased in the former case since the donation of electron density from the unoccupied $Al3sp^3$ HO to each $Al-H-Al$-bond MO and $Al-C-Al$-bond MO permits the participating orbital to decrease in size and energy.

To match the energies of the AOs and MOs of the ionic functional group with the others within the molecular ion, the bonding in organic ions comprises a standard bond that serves as basis element and retains the same geometrical characteristics as that standard bond. In the case of organic oxyanions, the $A-O^-$ ($A=C,S,N,P,Si$) bond is intermediate between a single and double bond, and the latter serves as a basis element. Similar to the case of the $C\overset{3e}{=}C$ aromatic bond wherein ethylene is the basis element, the $A=O$-bond functional group serves as the basis element for the $A-O^-$ functional group of the oxyanion of carboxylates, sulfates, nitrates, phosphates, silanolates, and siloxanolates. This oxyanion group designated by $A\overset{3e}{=}O^-$ comprises $(0.75)(4)=3$ electrons after Eq. (15.161). Thus, the energy parameters of the $A\overset{3e}{=}O^-$ functional group are given by the factor of $(0.75)(4)=3$ times those of the corresponding $A=O$ functional group, and the geometric parameters are the same. The $C=O$, $S=O$, $N=O_2$, $P=O$, and $Si=O$ basis elements are given in the Carboxylic Acids, Sulfates, Alkyl Nitrates, Phosphates, and Silicon Oxides, Silicic Acids, Silanols, Siloxanes and Disiloxanes sections, respectively. A convenient means to obtain the final group energy parameters of $E_T(Group)$ and $E_D(Group)$ is by using Eqs. (15.165-15.166) with $f_1=0.75$:

$$E_T\,(Group) = f_1\left(\begin{array}{l} E(basis\ energies) + E_T\left(atom - atom, msp^3.AO\right) \\ -31.63536831\ eV\sqrt{\dfrac{2\hbar\sqrt{\dfrac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_o R^3}}}{m_e c^2}} + n_1\bar{E}_{Kvib} + c_3\dfrac{8\pi\mu_o\mu_B^2}{r^3} \end{array}\right) \tag{15.183}$$

$$E_D\,(Group) = -\left(\begin{array}{l} f_1\left(\begin{array}{l} E(basis\ energies) + E_T\left(atom - atom, msp^3.AO\right) \\ -31.63536831\ eV\sqrt{\dfrac{2\hbar\sqrt{\dfrac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_o R^3}}}{m_e c^2}} + n_1\bar{E}_{Kvib} + c_3\dfrac{8\pi\mu_o\mu_B^2}{r^3} \end{array}\right) \\ -\left(c_4 E_{initial}\left(AO/HO\right) + c_5 E_{initial}\left(c_5\ AO/HO\right)\right) \end{array}\right) \tag{15.184}$$

where c_4 is $(0.75)(4) = 3$ when $c_5 = 0$ and otherwise c_4 is $(0.75)(2) = 1.5$ and c_5 is $(0.75)(2) = 1.5$.

The nature of the bonding of the amino functional group of protonated amines is similar to that in H_3^+. As given in the Triatomic Molecular Hydrogen-type Ion (H_3^+) section, H_3^+ comprises two indistinguishable spin-paired electrons bound by three protons. The ellipsoidal molecular orbital (MO) satisfies the boundary constraints as shown in the Nature of the Chemical Bond of Hydrogen-Type Molecules section. Since the protons are indistinguishable, ellipsoidal MOs about each pair of protons taken one at a time are indistinguishable. H_3^+ is then given by a superposition or linear combinations of three equivalent ellipsoidal MOs that form an equilateral triangle where the points of contact between the prolate spheroids are equivalent in energy and charge density. Due to the equivalence of the H_2-type ellipsoidal MOs and the linear superposition of their energies, the energy components defined previously for the H_2 molecule, Eqs. (11.207-11.212) apply in the case of the corresponding H_3^+ molecular ion. And, each molecular energy component is given by the integral of corresponding force in Eq. (13.5). Each energy component is the total for the two equivalent electrons with the exception that the total charge of the two electrons is normalized over the three basis set H_2-type ellipsoidal MOs. Thus, the energies (Eqs. (13.12-13.17)) are those given in the Energies of Hydrogen-Type Molecules section with the electron charge, where it appears, multiplied by a factor of $3/2$, and the three sets of equivalent proton-proton pairs give rise to a factor of three times the proton-proton repulsion energy given by Eq. (11.208).

With the protonation of the imidogen (NH) functional group, the minimum energy structure with equivalent hydrogen atoms comprises two protons bound to N by two paired electrons, one from H and one from N with the MO matched to the $N2p$ AO. These two electrons are distributed equivalently over the two $H-N$ bonds of the group such that the electron number assignable to each bond is $\frac{2}{2}$. Thus, the NH_2^+ functional group has the imidogen energy parameters with the exception that each energy term is multiplied by the factor 2 due to the two bonds with electron-number per bond of $\frac{2}{2}$ and has the same geometric parameters as the NH functional group given in the Secondary Amines section. A convenient means to obtain the final group energy parameters of $E_T\,(Group)$ and $E_D\,(Group)$ is by using Eqs. (15.165-15.166) (Eqs. (15.183-15.184)) with $f_1 = 2$ and c_4 and c_5 multiplied by two.

With the protonation of the amidogen (NH_2) functional group, the minimum energy structure with equivalent hydrogen atoms comprises three protons bound to N by four paired electrons, two from $2H$ and two from N with the MO matched to the $N2p$ AO. These four electrons are distributed equivalently over the three $H-N$ bonds of the group such that the electron number assignable to each bond is $\frac{4}{3}$. Thus, the NH_3^+ functional group has the amidogen energy parameters with the exception that each energy term is multiplied by the factor $\frac{3}{2}$ due to the three bonds with electron-number per bond of $\frac{4}{3}$ and has the same geometric parameters as the NH_2 functional group given in the Primary Amines section. A convenient means to obtain the final group energy parameters of $E_T\,(Group)$ and $E_D\,(Group)$ is by using Eqs. (15.165-15.166) (Eqs. (15.183-15.184)) with $f_1 = 3/2$ and c_4 and c_5 multiplied by 3/2.

The symbols of the functional groups of organic and related ions are given in Table 15.375. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters are given in Tables 15.376, 15.377, and 15.378, respectively. Due to its charge, the bond angles of the organic and related ions that minimize the total energy are those that maximize the separation of the groups. For ions having three bonds to the central atom, the angles are 120°, and ions having four bonds are tetrahedral. The color scale, charge-density of exemplary organic ion, protonated lysine, comprising atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.64.

Figure 15.64. Color scale, charge-density of protonated lysine ion showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei.

MONOSACCHARIDES OF DNA AND RNA

The simple sugar moiety of DNA and RNA comprises the alpha forms of 2-deoxy-D-ribose and D-ribose, respectively. The sugars comprise the alkyl CH_2, CH, and $C-C$ functional groups and the alkyl alcohol $C-O$ and OH functional groups given in the Alcohols section. In addition, the alpha form of the sugars comprise the $C-O$ ether functional group given in the Ethers section, and the open-chain forms further comprise the carbon to carbonyl $C-C$, the methylyne carbon of the aldehyde carbonyl CH, and the aldehyde carbonyl $C=O$ functional groups given in the Aldehydes section. The total energy of each sugar given in Tables 15.379-15.382 was calculated as the sum over the integer multiple of each $E_D(Group)$ corresponding to the functional-group composition wherein the group identity and energy $E_D(Group)$ are given in each table. The color scale, charge-density of the monosaccharides, each comprising atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figure 15.65.

Figure 15.65. Color scale, charge-density of riboses showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (A) 2-deoxy-D-ribose. (B) D-ribose. (C) Alpha-2-deoxy-D-ribose. (D) Alpha-D-ribose.

NUCLEOTIDE BONDS OF DNA AND RNA

DNA and RNA comprise a backbone of alpha-2-deoxy-D-ribose and alpha-D-ribose, respectively, with a charged phosphate moiety at the 3' and 5' positions of two consecutive ribose units in the chain and a base bound at the 1' position wherein the ribose H of each of the corresponding 3' or 5' $O-H$ and 1' $C-H$ bonds is replaced by P and the base N, respectively. For the base, the H of the $N-H$ at the pyrimidine 1 position or the purine 9 position is replaced by the sugar C. The basic repeating unit of DNA or RNA is a nucleotide that comprises a monosaccharide, a phosphate moiety and a base. The structure of the nucleotide bond is shown in Figure 15.66 with the designation of the corresponding atoms. The phosphate moiety comprises the $P=O$, $P-O$, and $C-O$ functional groups given in the Phosphates section as well as the $P-O^-$ group given in the Organic and Related Ions section. The nucleoside bond (sugar C to base N) comprises the tertiary amine $C-N$ functional group given in the corresponding section. The bases, adenine, guanine, thymine, and cytosine are equivalent to those given in the corresponding sections. The symbols of the functional groups of the nucleotide bond are given in Table 15.383. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters are given in Tables 15.384, 15.385, and 15.386, respectively. The functional group composition and the corresponding energy $E_D(Group)$ of each group of the nucleotide bond of DNA and RNA are given in Table 15.387. The bond angle parameters of the nucleoside bond determined using Eqs. (15.88-15.117) are given in Table 15.388. The color scale rendering of the charge-density of the exemplary tetra-nucleotide, (deoxy)adenosine 3'-monophosphate—5'-(deoxy)thymidine 3'-monophosphate—5'-(deoxy)guanosine 3'-monophosphate—5'-(deoxy)cytidine monophosphate (ATGC) comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.67. Figure 15.68 shows the color scale rendering of the charge-density of the exemplary DNA fragment $\begin{matrix}\text{ACTGACTGACTG}\\ \text{TGACTGACTGAC}\end{matrix}$ wherein each complementary strand comprises a dodeca-nucleotide of the form (base (1)—deoxyribose) monophosphate—(base(2)—deoxyribose) monophosphate— with the phosphates bridging the 3' and 5' ribose carbons with the opposite order for the complementary stands. Figure 15.68 shows the color scale rendering of the charge-density of an exemplary double-stranded DNA helix.

Figure 15.66. Designation of the atoms of the nucleotide bond.

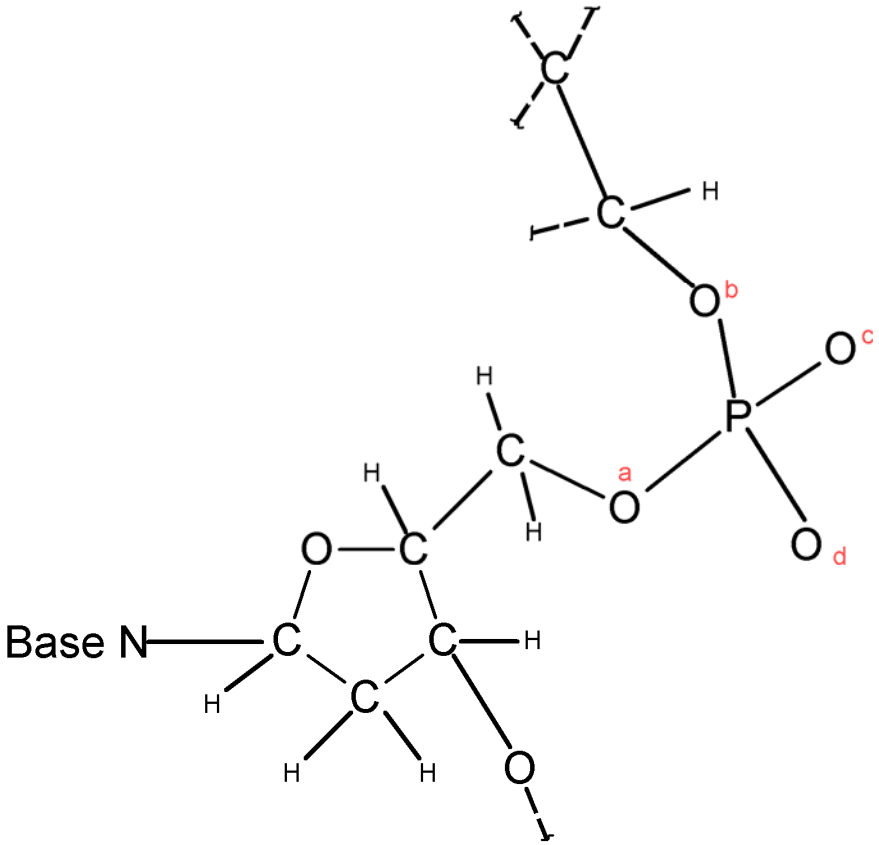

Figure 15.67. The color scale rendering of the charge-density of the exemplary tetra-nucleotide, (deoxy)adenosine monophosphate—(deoxy)thymidine monophosphate—(deoxy)guanosine monophosphate—(deoxy)cytidine monophosphate (ATGC) showing the orbitals of the atoms at their radii and the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond.

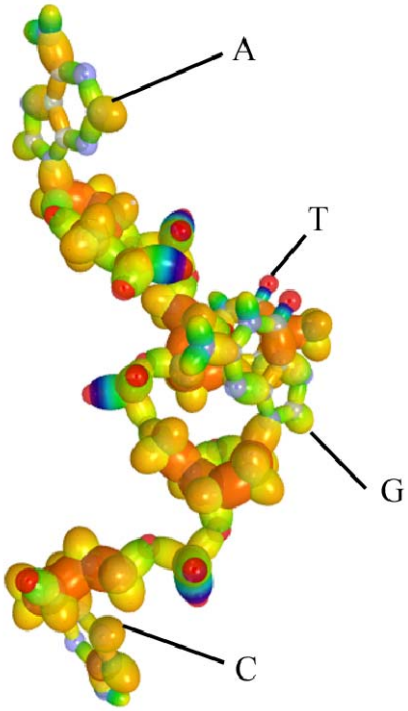

Figure 15.68. Color scale rendering of the charge-density of the DNA fragment ACTGACTGACTG TGACTGACTGAC showing the orbitals of the atoms at their radii and the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond.

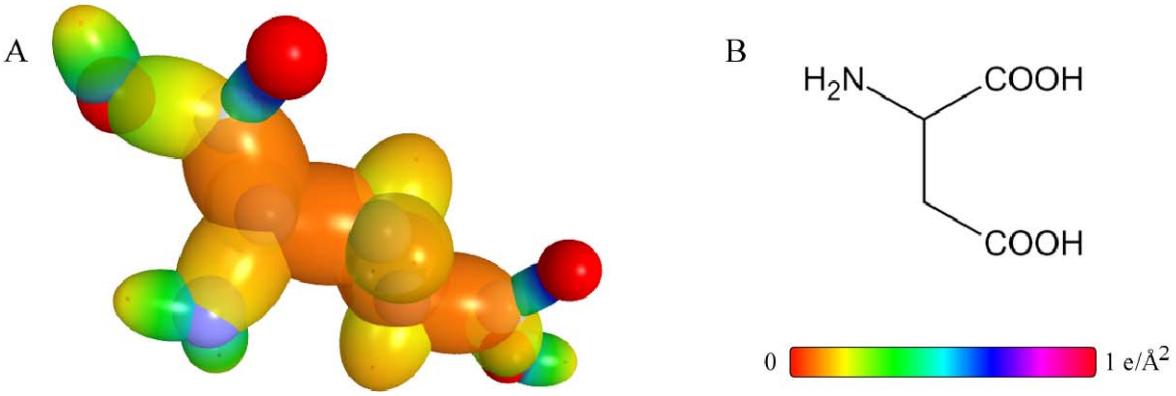
AMINO ACIDS ($H_2N-CH(R)-COOH$)

The amino acids, $H_2NCH(R)COOH$, each have a primary amine moiety comprised of NH_2 and $C-N$ functional groups, an alkyl carboxylic acid moiety comprised of a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. The carboxylic acid moiety further comprises a $C-OH$ moiety that comprises $C-O$ and OH functional groups. The alpha carbon comprises a methylyne (CH) functional group bound to a side chain R group by an isopropyl $C-C$ bond functional group. These groups common to all amino acids are given in the Primary Amines section, the Carboxylic Acids section, and the Branched Alkanes section, respectively. The R group is unique for each amino acid and determines its characteristic hydrophilic, hydrophobic, acidic, and basic properties. These characteristic functional groups are given in the prior organic functional group sections. The total energy of each amino acid given in Tables 15.389-15.408 was calculated as the sum over the integer multiple of each $E_D(Group)$ corresponding to the functional-group composition of the amino acid wherein the group identity and energy $E_D(Group)$ are given in each table. The structure and the color scale, charge-density of the amino acids, each comprising atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs are shown in Figures 15.70-15.89.

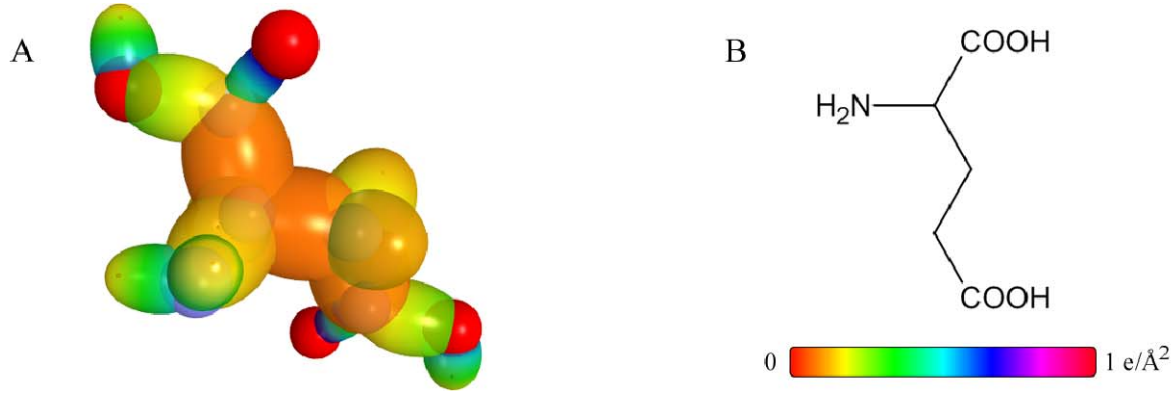
ASPARTIC ACID

Figure 15.70. (A) Color scale, charge-density of aspartic acid showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure of aspartic acid.



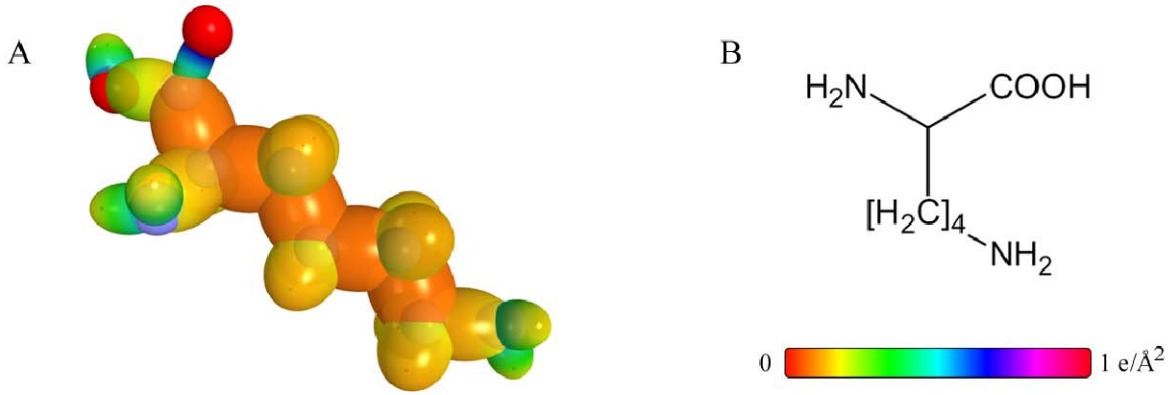
GLUTAMIC ACID

Figure 15.71. (A) Color scale, charge-density of glutamic acid showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure of glutamic acid.



CYSTEINE

Figure 15.72. (A) Color scale, charge-density of cysteine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure of cysteine.



LYSINE

Figure 15.73. (A) Color scale, charge-density of lysine showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei. (B) Chemical structure of lysine.

POLYPEPTIDES $(-\left[HN-CH(R)-C(O)\right]_n-)$

The amino acids can be polymerized by reaction of the OH group from the carboxylic acid moiety of one amino acid with H from the alpha-carbon NH_2 of another amino acid to form H_2O and an amide bond as part of a polyamide chain of a polypeptide or protein. Each amide bond that forms by the condensation of two amino acids is called a peptide bond. It comprises a $C=O$ functional group, and the single bond of carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group. The peptide bond further comprises a $C-NH\left(R\right)$ moiety that comprises NH and $C-N$ functional groups where R is the characteristic side chain of each amino acid that is unchanged in terms of its functional group composition upon the formation of the peptide bond. From the N-Alkyl and N,N-Dialkyl-Amides section, the functional group composition and the corresponding energy $E_D\,(Group)$ of each group of the peptide bond is given in Table 15.409. The color scale, charge-density of the exemplary polypeptide, phenylalanine-leucine-glutamine-asparic acid (phe-leu-gln-asp) comprising the atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 15.90. The color scale, opaque view of the charge-density of the exemplary protein bovine pancreatic trypsin inhibitor (BPTI) is shown in Figure 15.91.

Figure 15.90. Color scale, charge-density of the polypeptide phenylalanine-leucine-glutamine-aspartic acid (phe-leu-gln-asp) showing the orbitals of the atoms at their radii and the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond.

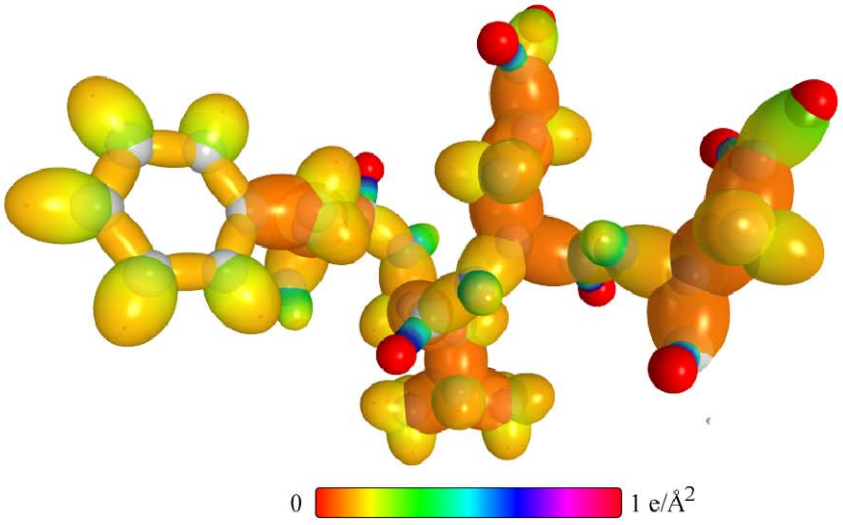

Figure 15.91. Color scale, opaque view of the charge-density of bovine pancreatic trypsin inhibitor (BPTI) protein created and modeled using Millsian 2.0. BPTI has been used as a medication administered by injection to reduce bleeding during complex surgery, such as heart and liver surgery. Its main effect is the inhibition of fibrinolysis, the process that leads to the breakdown of blood clots. The aim in its use is to decrease the need for blood transfusions during surgery, as well as end-organ damage due to hypotension (low blood pressure) as a result of marked blood loss. However, this drug was temporarily withdrawn worldwide in 2007 after studies suggested that its use increased the risk of complications or death. This protein is usually used as the benchmark for bimolecular modeling method and with accurate knowledge of its structure, it is possible to engineer it to avoid its prior side effects.

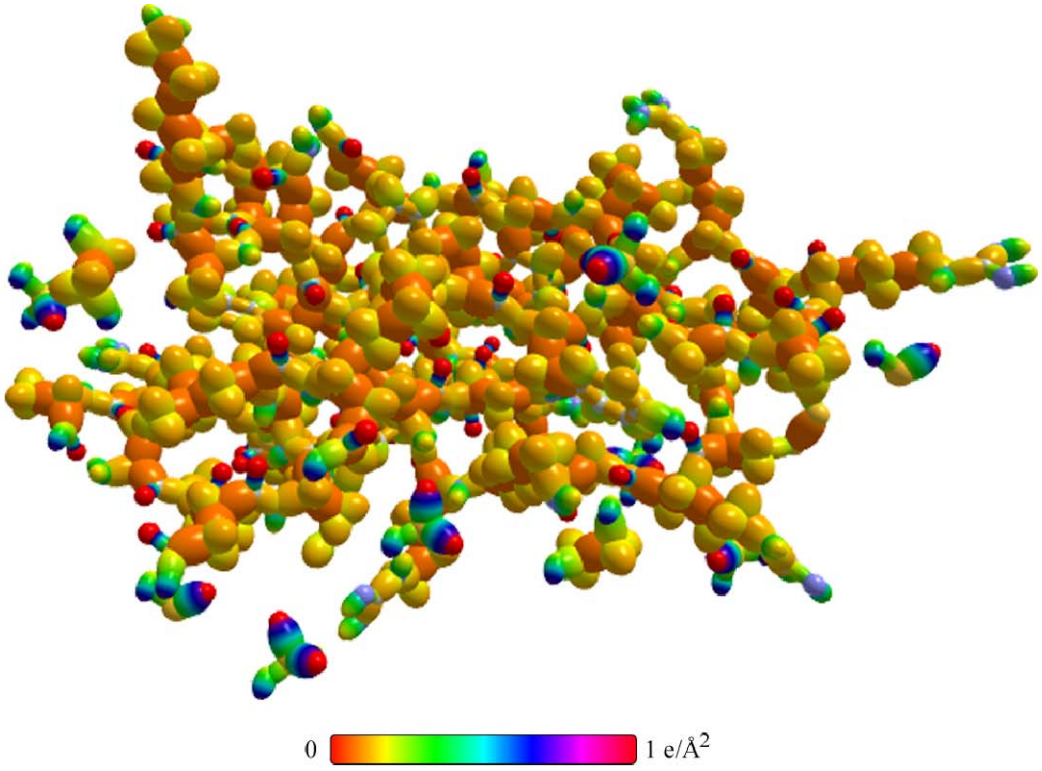

Table 15.409. The functional group composition and the energy $E_D(Group)$ of each group of the peptide bond.

Formula	$C-C(O)$ (alkyl amide) Group	$C-N$ ($(O)C$-N alkyl amide) Group	$C-N$ (N alkyl amide) Group	NH (N alkyl amide) Group

Table 15.410.43. Summary results of amino acids.

Formula	Name	Calculated Total Bond Energy (eV)	Experimental Total Bond Energy (eV)	Relative Error
$C_4H_7NO_4$	aspartic acid	68.98109	70.843[a]	0.02628
$C_5H_9NO_4$	glutamic acid	81.13879	83.167[a]	0.02438
$C_3H_7NO_4S$	cysteine	55.02457	56.571[a]	0.02733
$C_6H_{14}N_2O_2$	lysine	95.77799	98.194[a]	0.02461
$C_6H_{14}N_2O_2$	arginine	105.07007	107.420[a]	0.02188
$C_6H_9N_3O_2$	histidine	88.10232	89.599[a]	0.01671
$C_4H_8N_2O_2$	asparagine	71.57414	73.513[a]	0.02637
$C_5H_{10}N_2O_2$	glutamine	83.73184	85.843[a]	0.02459
$C_4H_9NO_3$	threonine	68.95678	71.058[a]	0.02956
$C_9H_{11}NO_3$	tyrosine	109.40427	111.450[a]	0.01835
$C_3H_7NO_3$	serine	56.66986	58.339[a]	0.02861
$C_{11}H_{12}N_2O_2$	tryptophan	126.74291	128.084[a]	0.01047
$C_9H_{11}NO_2$	phenylalanine	104.90618	105.009	0.00098
$C_5H_9NO_2$	proline	71.76826	71.332	-0.00611
$C_5H_9NO_2$	methionine	79.23631	79.214	-0.00028
$C_6H_{13}NO_2$	leucine	89.12115	89.047	-0.00083
$C_6H_{13}NO_2$	isoleucine	89.02978	90.612	0.01746
$C_6H_{13}NO_2$	valine	76.87208	76.772	-0.00130
$C_3H_7NO_2$	alanine	52.57549	52.991	0.00785
$C_2H_5NO_2$	glycine	40.28857	40.280	-0.00021

Chapter 16

APPLICATIONS: PHARMACEUTICALS, SPECIALTY MOLECULAR FUNCTIONAL GROUPS AND MOLECULES, DIPOLE MOMENTS AND INTERACTIONS

GENERAL CONSIDERATIONS OF THE BONDING IN PHARMACEUTICALS AND SPECIALTY MOLECULES

Pharmaceutical and specialty molecules comprising an arbitrary number of atoms can be solved using similar principles and procedures as those used to solve general organic molecules of arbitrary length and complexity. Pharmaceuticals and specialty molecules can be considered to be comprised of functional groups such as those of alkanes, branched alkanes, alkenes, branched alkenes, alkynes, alkyl fluorides, alkyl chlorides, alkyl bromides, alkyl iodides, alkene halides, primary alcohols, secondary alcohols, tertiary alcohols, ethers, primary amines, secondary amines, tertiary amines, aldehydes, ketones, carboxylic acids, carboxylic esters, amides, N-alkyl amides, N,N-dialkyl amides, ureas, acid halides, acid anhydrides, nitriles, thiols, sulfides, disulfides, sulfoxides, sulfones, sulfites, sulfates, nitro alkanes, nitrites, nitrates, conjugated polyenes, aromatics, heterocyclic aromatics, substituted aromatics, and others given in the Organic Molecular Functional Groups and Molecules section. The solutions of the functional groups can be conveniently obtained by using generalized forms of the geometrical and energy equations. The functional-group solutions can be made into a linear superposition and sum, respectively, to give the solution of any pharmaceutical or specialty molecule comprising these groups. The total bond energies of exemplary pharmaceutical or specialty molecules such as aspirin, RDX, and NaH are calculated using the functional group composition and the corresponding energies derived in the previous sections as well as those of any new component functional groups derived herein.

ASPIRIN (ACETYLSALICYLIC ACID)

Aspirin comprises salicylic acid (ortho-hydroxybenzoic acid) with the H of the phenolic OH group replaced by an acetyl group. Thus, aspirin comprises the benzoic acid $C-C(O)-OH$ moiety that comprises $C=O$ and OH functional groups that are the same as those of carboxylic acids given in the corresponding section. The single bond of aryl carbon to the carbonyl carbon atom, $C-C(O)$, is also a functional group given in the Benzoic Acid Compounds section. The aromatic $C\overset{3e}{=}C$ and $C-H$ functional groups are equivalent to those of benzene given in the Aromatic and Heterocyclic Compounds section. The phenolic ester $C-O$ functional group is equivalent to that given in the Phenol section. The acetyl $O-C(O)-CH_3$ moiety comprises (i) $C=O$ and $C-C$ functional groups that are the same as those of carboxylic acids and esters given in the corresponding sections, (ii) a CH_3 group that is equivalent to that of alkanes given in the corresponding sections, (iii) and a $C-O$ bridging the carbonyl carbon and the phenolic ester which is equivalent to that of esters given in the corresponding section.

The symbols of the functional groups of aspirin are given in Table 16.1.

The corresponding designations of aspirin are shown in Figure 16.1B. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of aspirin are given in Tables 16.2, 16.3, and 16.4, respectively. The total energy of aspirin given in Table 16.5 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 16.4 corresponding to functional-group composition of the molecule. The bond angle parameters of aspirin determined using Eqs. (15.88-15.117) are given in Table 16.6. The color scale, translucent view of the charge density of aspirin comprising the concentric shells of atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 16.1A.

Figure 16.1. (A) Color scale, translucent view of the charge density of aspirin showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale). (B) Chemical structure and designation of aspirin.

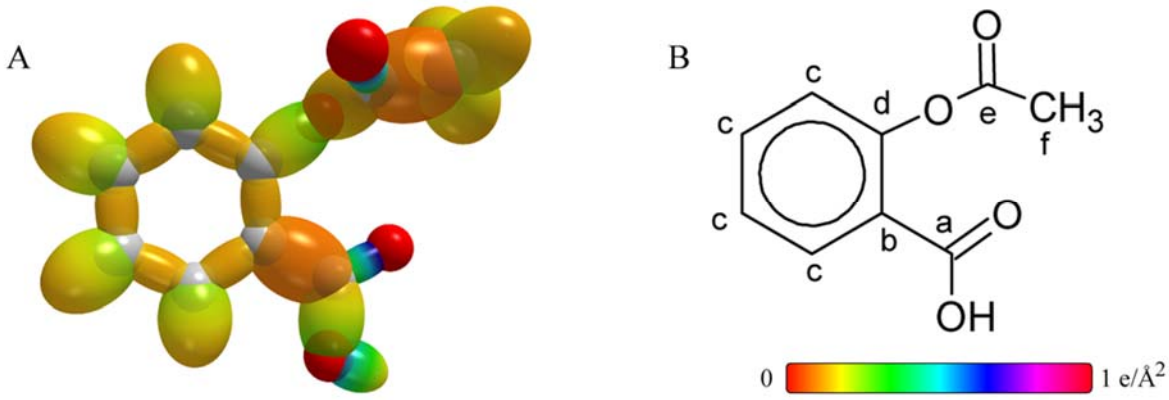

Table 16.1. The symbols of functional groups of aspirin.

Functional Group	Group Symbol
CC (aromatic bond)	$C\overset{3e}{=}C$
CH (aromatic)	*CH*
Aryl *C*-*C*(*O*)	$C-C(O)$ (i)
Alkyl *C*-*C*(*O*)	$C-C(O)$ (ii)
C=*O* (aryl carboxylic acid)	$C=O$
Aryl (*O*)*C*-*O*	$C-O$ (i)
Alkyl (*O*)*C*-*O*	$C-O$ (ii)
Aryl *C*-*O*	$C-O$ (iii)
OH group	*OH*
CH_3 group	CH_3

CYCLOTRIMETHYLENE-TRINITRAMINE ($C_3H_6N_6O_6$)

The compound cyclotrimethylene-trinitramine, commonly referred to as Cyclonite or by the code designation RDX, is a well-known explosive. RDX comprises three methylene (CH_2) groups joined by six alkyl $C-N$ secondary amine functional groups given in the corresponding section. Each of the three N's of the six-membered ring shown in Figure 16.2B is bonded to a NO_2 functional group given in the Nitroalkanes section by a $N-N$ functional group. The latter requires hybridization of the nitrogen atoms in order to match the energies of the bridged groups.

Similar to the case of carbon, silicon, and aluminum, the bonding in the nitrogen of the $N-N$ functional group involves four sp^3 hybridized orbitals formed from the outer $2p$ and $2s$ shells. In RDX, bonds form between two $N2sp^3$ HOs ($N-N$ functional group), between a $N2sp^3$ HO and a $C2sp^3$ HO ($C-N$ functional group), and between a $N2sp^3$ HO and a $O2p$ AO (each $N-O$ bond of the NO_2 functional group). The geometrical and energy equations of the $N-N$ functional group are given in the Derivation of the General Geometrical and Energy Equations of Organic Chemistry section wherein the energy is matched to $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)).

The $2sp^3$ hybridized orbital arrangement after Eq. (13.422) is:

$$\begin{array}{cccc} & 2\text{sp}^3 \text{ state} & & \\ \uparrow\downarrow & \uparrow & \uparrow & \uparrow \\ \hline 0,0 & 1,-1 & 1,0 & 1,1 \end{array} \tag{16.1}$$

where the quantum numbers (ℓ,m_ℓ) are below each electron. The total energy of the state is given by the sum over the five electrons. The sum $E_T\left(N,2sp^3\right)$ of experimental energies [15] of N, N^+, N^{2+}, N^{3+}, and N^{4+} is:

$$\begin{aligned} E_T\left(N,2sp^3\right) &= -\begin{pmatrix} 97.8902\ eV+77.4735\ eV+47.44924\ eV \\ +29.6013\ eV+14.53414\ eV \end{pmatrix} \\ &= -266.94838\ eV \end{aligned} \tag{16.2}$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius r_{2sp^3} of the $N2sp^3$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$r_{2sp^3}=\sum_{n=2}^{6}\frac{(Z-n)e^2}{8\pi\varepsilon_0\left(e266.94838\ eV\right)}=\frac{15e^2}{8\pi\varepsilon_0\left(e266.94838\ eV\right)}=0.76452a_0 \tag{16.3}$$

where $Z=7$ for nitrogen. Using Eq. (15.14), the Coulombic energy $E_{Coulomb}\left(N,2sp^3\right)$ of the outer electron of the $N2sp^3$ shell is:

$$E_{Coulomb}\left(N,2sp^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{2sp^3}}=\frac{-e^2}{8\pi\varepsilon_0 0.76452a_0}=-17.79656\ eV \tag{16.4}$$

In RDX, the $C2sp^3$ HO has a hybridization factor of 0.91771 (Eq. (13.430)) with a corresponding energy of $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)), and the N HO has an energy of $E\left(N,2sp^3\right)=-17.79656\ eV$ (Eq. (16.4)). To meet the equipotential, minimum-energy condition of the union of the $N2sp^3$ and $C2sp^3$ HOs, $C_2=1$ in Eqs. (15.2-15.5), (15.51), and (15.61) for the $N-N$-bond MO, and c_2 given by Eqs. (15.77) and (15.79) is:

$$c_2\left(C2sp^3HO\ to\ N_b2sp^3HO\ to\ N_a2sp^3HO\right)=\frac{E\left(C,2sp^3\right)}{E\left(N,2sp^3\right)}c_2\left(C2sp^3HO\right)=\frac{-14.63489\ eV}{-17.79656\ eV}\left(0.91771\right)=0.75468 \tag{16.5}$$

The energy of the $N-N$-bond MO is the sum of the component energies of the H_2-type ellipsoidal MO given in Eq. (15.51). Since the energy of the MO is matched to that of the $C2sp^3$ HO, $E\left(AO/HO\right)$ in Eqs. (15.51) and (15.61) is: $E\left(C,2sp^3\right)=-14.63489\ eV$ given by Eq. (15.25) and $E_T\left(atom-atom,msp^3.AO\right)$ is $0\ eV$.

The symbols of the functional groups of RDX are given in Table 16.7. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of RDX are given in Tables 16.8, 16.9, and 16.10, respectively. The total energy of RDX given in Table 16.11 was calculated as the sum over the integer multiple of each $E_{D(Group)}$ of Table 16.10 corresponding to functional-group composition of the molecule. The bond angle parameters of RDX determined using Eqs. (15.88-15.117) are given in Table 16.12. The color scale charge density of RDX comprising atoms with the outer shell bridged by one or more H_2-type ellipsoidal MOs or joined with one or more hydrogen MOs is shown in Figure 16.2A.

Figure 16.2. (A) Color scale charge density of RDX showing the outer orbitals of the atoms at their radii and the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond. (B) Chemical structure and atom designation of RDX.

SODIUM HYDRIDE MOLECULE (NaH)

Alkali hydride molecules each comprising an alkali metal atom and a hydrogen atom can be solved using similar principles and procedures as those used to solve organic molecules. The solutions of these molecules can be conveniently obtained by using generalized forms of the force balance equation given in the Force Balance of the σ MO of the Carbon Nitride Radical section and the geometrical and energy equations given in the Derivation of the General Geometrical and Energy Equations of Organic Chemistry section.

The bonding in the sodium atom involves the outer $3s$ atomic orbital (AO), and the $Na-H$ bond forms between the $Na3s$ AO and the $H1s$ AO. The energy of the reactive outer electron of the sodium atom is significantly less than the Coulombic energy between the electron and proton of H given by Eq. (1.276). Consequently, the outer electron comprising the $Na3s$ AO and the $H1s$ AO form a σ-MO, and the inner AOs of Na remain unaltered. The MO semimajor axis of molecular sodium hydride is determined from the force balance equation of the centrifugal, Coulombic, and magnetic forces as given in the Polyatomic Molecular Ions and Molecules section and the More Polyatomic Molecules and Hydrocarbons section. Then, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) wherein the distance from the origin of the H_2-type-ellipsoidal-MO to each focus c', the internuclear distance $2c'$, and the length of the semiminor axis of the prolate spheroidal H_2-type MO $b=c$ are solved from the semimajor axis a.

The force balance of the centrifugal force equated to the Coulombic and magnetic forces is solved for the length of the semimajor axis. The Coulombic force on the pairing electron of the MO is:

$$\mathbf{F}_{Coulomb}=\frac{e^2}{8\pi\varepsilon_0 ab^2}D\mathbf{i}_\xi \tag{16.6}$$

The spin pairing force is

$$\mathbf{F}_{spin-pairing}=\frac{\hbar^2}{2m_e a^2b^2}D\mathbf{i}_\xi \tag{16.7}$$

The diamagnetic force is:

$$\mathbf{F}_{diamagneticMO1}=-\frac{n_e\hbar^2}{4m_e a^2b^2}D\mathbf{i}_\xi \tag{16.8}$$

where n_e is the total number of electrons that interact with the binding σ-MO electron. The diamagnetic force $\mathbf{F}_{diamagneticMO2}$ on the pairing electron of the σ MO is given by the sum of the contributions over the components of angular momentum:

$$\mathbf{F}_{diamagneticMO2}=-\sum_{i,j}\frac{|L_i|\hbar}{Z_j 2m_e a^2b^2}D\mathbf{i}_\xi \tag{16.9}$$

where $|L|$ is the magnitude of the angular momentum of each atom at a focus that is the source of the diamagnetism at the σ-MO. The centrifugal force is:

$$\mathbf{F}_{centrifugalMO}=-\frac{\hbar^2}{m_e a^2b^2}D\mathbf{i}_\xi \tag{16.10}$$

The force balance equation for the σ-MO of the $Na-H$-bond MO with $n_e=2$ and $|L|=\left(2+\sqrt{\frac{3}{4}}\right)\hbar$ is:

$$\frac{\hbar^2}{m_e a^2b^2}D=\frac{e^2}{8\pi\varepsilon_0 ab^2}D+\frac{\hbar^2}{2m_e a^2b^2}D-\left(\frac{2}{2}+\frac{2}{Z}+\frac{\sqrt{\frac{3}{4}}}{Z}\right)\frac{\hbar^2}{2m_e a^2b^2}D \tag{16.11}$$

$$a=\left(2+\frac{2}{Z}+\frac{\sqrt{\frac{3}{4}}}{Z}\right)a_0 \tag{16.12}$$

With $Z=11$, the semimajor axis of the $Na-H$-bond MO is:

$$a=2.26055a_0 \tag{16.13}$$

Using the semimajor axis, the geometric and energy parameters of the MO are calculated using Eqs. (15.1-15.117) in the same manner as the organic functional groups given in the Organic Molecular Functional Groups and Molecules section. For the $Na-H$-bond MO of the NaH, $c_1=1$, $c_2=1$ and $C_2=1$ in both the geometry relationships (Eqs. (15.2-15.5)) and the energy equation (Eq. (15.61)). In NaH the molecule, the $Na3s$ AO has an energy of $E(Na3s)=-5.139076\ eV$ [15] and the H AO has an energy of $E(H)=-13.59844\ eV$ [15]. To meet the equipotential condition of the union of the $Na3s$ AO and the $H1s$ AO, c_2 and C_2 of Eqs. (15.2-15.5) and Eq. (15.61) for the $Na-H$-bond MO given by Eq. (15.77) is:

$$C_2\left(Na3s\ AO\ to\ H1s\ AO\right)=c_2\left(Na3s\ AO\ to\ H1s\ AO\right)=\frac{-5.139076\ eV}{-13.59844\ eV}=0.37792 \tag{16.14}$$

The energy of the MO is matched to that of the $Na2p$ AO with which it intersects such that $E\left(AO/HO\right)$ is $E\left(Na2p\right)=-47.2864\ eV$ [15]; thus, $E_{initial}\left(c_4\ AO/HO\right)\ (eV)$ is given by the sum of $E\left(Na2p\right)=-47.2864\ eV$ and $E\left(Na3s\right)=-5.139076\ eV$.

The symbol of the functional group of molecular NaH is given in Table 16.13. The geometrical (Eqs. (15.1-15.5) and (16.11-16.14)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.61-15.65) and (16.13-16.14)) parameters of molecular NaH are given in Tables 16.14, 16.15, and 16.16, respectively. The color scale, translucent view of the charge-densities of molecular NaH comprising the concentric shells of the inner AOs of the Na atom and an outer MO formed from the outer $Na3s$ AO and the $H1s$ AO are shown in Figure 16.3.

Figure 16.3. Color scale, translucent view of the charge-densities of molecular NaH showing the inner orbitals of the Na atom at their radii, the ellipsoidal surface of the H_2-type ellipsoidal MO formed from the outer $Na3s$ AO and the $H1s$ AO H, and the hydrogen nucleus (red, not to scale).

BOND AND DIPOLE MOMENTS

The bond moment of a functional group may be calculated by considering the charge donation between atoms of the functional group. Since the potential of an MO is that of a point charge at infinity (Eq. (11.36)), an asymmetry in the distribution of charge between nonequivalent HOs or AOs of the MO occurs to maintain an energy match of the MO with the bridged orbitals. The charge must redistribute between the spherical orbitals to achieve a corresponding current-density that maintains constant current at the equivalent-energy condition according to the energy-matching factor such as c_2 or C_2 of Eqs. (15.51) and (15.61). Since the orbital energy and radius are reciprocally related, the contribution scales as the square of the ratio (over unity) of the energy of the resultant net positively-charged orbital and the initial matched energy of the resultant net negatively-charged orbital of the bond multiplied by the energy-matching factor (e.g. c_2 or C_2). The partial charges on the HOs or AOs corresponding to the charge contribution are equivalent to point charges centered on the nuclei. Due to symmetry, the bond moment μ of each functional group is along the internuclear axis and is calculated from the partial charges at the separation distance, the internuclear distance.

Using the reciprocal relationship between the orbital energies and radii, the dependence of the orbital area on the radius squared, and the relationship of the partial charge q to the areas with energy matching for each electron of the MO, the bond moment μ along the internuclear axis of $A-B$ wherein A is the net positively-charged atom is given by:

$$\mu = qd = n_1 ce\left(1-\left(\frac{E_A(valence)}{E_B(valence)}\right)^2\right)2c' \tag{16.15}$$

wherein n_1 is the number of equivalent bonds of the MO, c is energy-matching factor such as c_1, c_2, C_1, or C_2 of Eqs. (15.51) and (15.61) where c_1 and C_2 may correspond to both electrons of a MO localized on one AO or HO such as when the magnitude of the valence or Coulombic energy of the AO or HO is less than that of $E_{Coulomb}(H) = -13.605804\ eV$ or when the orbital may contain paired or shared electrons in a linear combination with the partner orbital, and d is the charge-separation distance, the internuclear distance $2c'$. $E_B(valence)$ is the initial matched energy of the resultant net negatively-charged orbital of the bond that is further lowered by bonding (Eqs. (15.32) and (15.16)) to atom A having an energy $E_A(valence)$. Typically, $E_B(valence)$ of a carbon-heteroatom bond is $-14.63489\ eV$, the initial $C2sp^3$ HO (Eq. (15.25)) energy to which the heteroatom is energy matched. Functional group bond moments determined using Eq. (16.15) are given in Table 16.17.

[a] The more positive atom is on the left.

[b] c_2 from Eqs. (15.77), (15.79), and Eq. (13.430) and $E_A(valence)$ is given by 1/2 two H_2-type ellipsoidal MOs (Eq. (11.212)).

[c] c_2 from Eqs. (15.77), (15.79), and the product of 0.936127 (Eq. (13.248)) and 0.92235 given by $13.59844\ eV / (13.59844\ eV + 0.25 \cdot E_D)$ where E_D is the $N-H$ bond energy $E_D\left({}^{14}NH_3\right) = 4.57913\ eV$ given by Eq. (13.404) and the energy of H is $13.59844\ eV$; $E_A(valence)$ is given by 1/2 two H_2-type ellipsoidal MOs (Eq. (11.212)).

[d] $E_A(valence)$ is given by 1/2 two H_2-type ellipsoidal MOs (Eq. (11.212)).

[e] c_2 from Eqs. (15.77) given by $13.59844\ eV / (13.59844\ eV + 0.25 \cdot E_D)$ where E_D is the $O-H$ bond energy $E_D(H^{16}OH) = 5.1059\ eV$ given by Eq. (13.222) and the energy of H is $13.59844\ eV$; $E_A(valence)$ is given by 1/2 two H_2-type ellipsoidal MOs (Eq. (11.212)).

[f] Eq. (15.129) with the inverse energy ratio of $E(F) = -17.42282\ eV$ and $E(C, 2sp^3) = -14.63489\ eV$ corresponding to the higher binding energy of the former.

[g] $E_A(valence)$ is given by $15.35946\ eV - 1/2E_{mag}$ (Eqs. (14.150) and (15.67)).

[h] c_1 from Eqs. (15.79), (15.145), and (13.430); $E_A(valence)$ is given by 1/2 two H_2-type ellipsoidal MOs (Eq. (11.212)).

[i] c_2 from the reciprocal of Eq. (15.147), $E_A(valence)$ is given by Eq. (15.139), and $E_B(valence)$ is $E(S) = -10.36001\ eV$.

[j] c_2 from the reciprocal of Eq. (15.182).

[k] c_2 from the reciprocal of Eq. (20.49).

[l] c_2 from the reciprocal of Eq. (22.29).

[m] c_2 from Eq. (15.77) using $E(F) = -17.42282\ eV$ and $E\left(B_{B-Fborane}, 2sp^3\right) = -14.88734\ eV$ (Eq. (22.61)).

The dipole moment of a given molecule is then given by the vector sum of the bond moments in the molecule. Thus, the dipole moment is given by taking into account the magnitude and direction of the bond moment of each functional group wherein the functional group bond moment stays constant from molecule to molecule and is in the vector direction of the internuclear axis. The dipole moments of water and ammonia to compare to the experimental values are given from the corresponding moments in Table 16.17. The calculated dipole moment of H_2O is:

$$\mu_{H_2O} = 2(1.51)\cos\left(\frac{106°}{2}\right) = 1.8128D \tag{16.16}$$

where the angle between the $O-H$ bond is 106° given by Eq. (13.242). The experimental dipole moment of H_2O is [23] :

$$\mu_{H_2O} = 1.8546D \tag{16.17}$$

The calculated dipole moment of NH_3 is:

$$\mu_{NH_3} = 3(1.30)\cos(68°) = 1.467D \tag{16.18}$$

where the angle between each $N-H$ bond and the z-axis is 68° given by Eq. (13.417). The experimental dipole moment of NH_3 is [23]:

$$\mu_{NH_3} = 1.4718D \tag{16.19}$$

The charge distributions of the functional groups given in Table 16.17 facilitate the rendering of the charge distribution of molecules of unlimited complexity comprised of these functional groups. What was previously impossible to achieve using supercomputers can be readily accomplished on a personal computer (PC). The rendering of the true charge densities of the exemplary proteins insulin and lysozyme are shown in color scale, opaque view in Figures 16.4 and 16.5, respectively. The color scale, opaque view of the charge density of an exemplary double-stranded RNA helix is shown in Figure 16.6.

Figure 16.4. Color scale, opaque view of the charge density of insulin created and modeled using Millsian 2.0 on a PC.

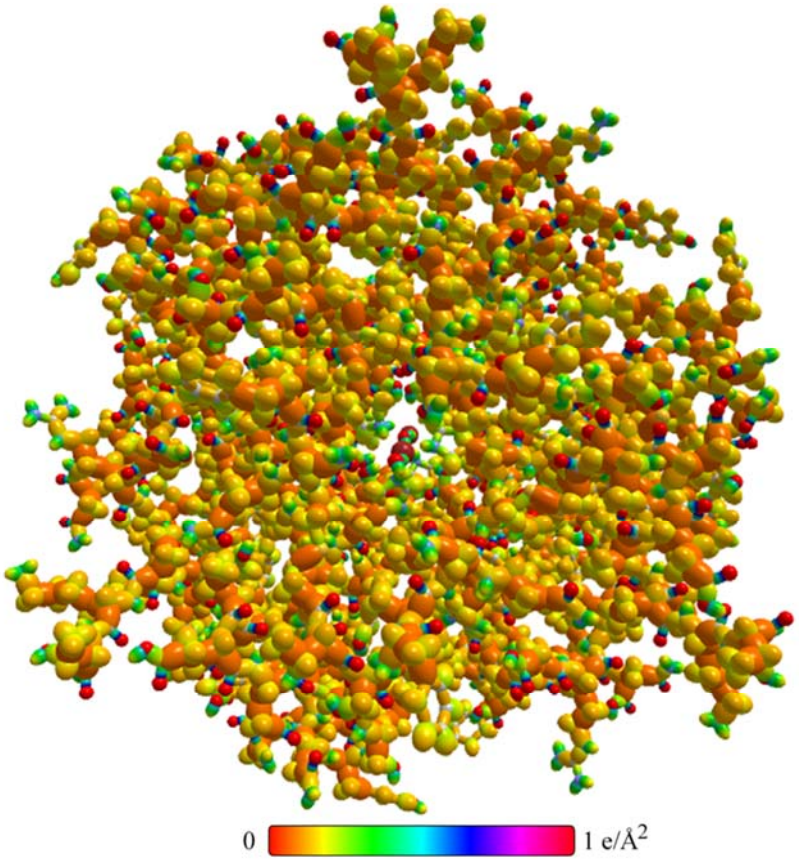

Figure 16.5. Color scale, opaque view of the charge density of lysozyme created and modeled using Millsian 2.0 on a PC.

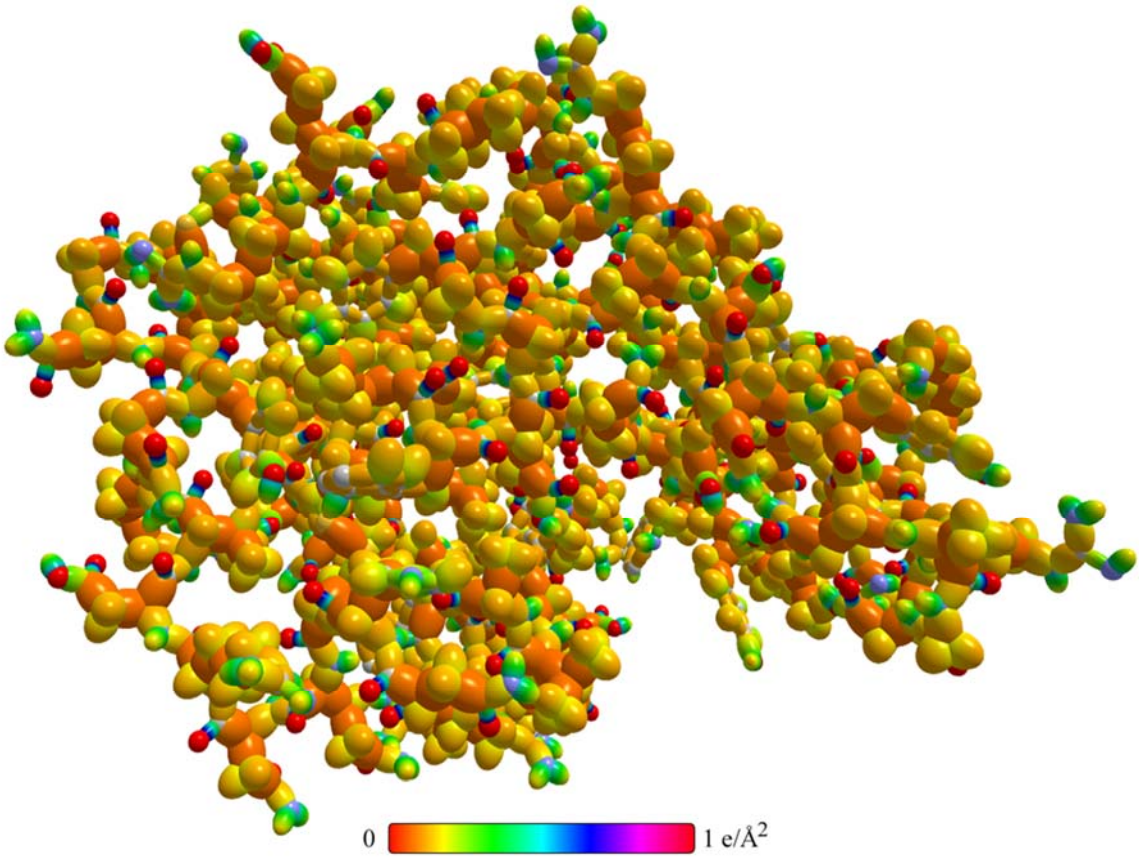

Figure 16.6. Color scale, opaque view of the charge density of a double-stranded DNA helix created and modeled using Millsian 2.0 on a PC.

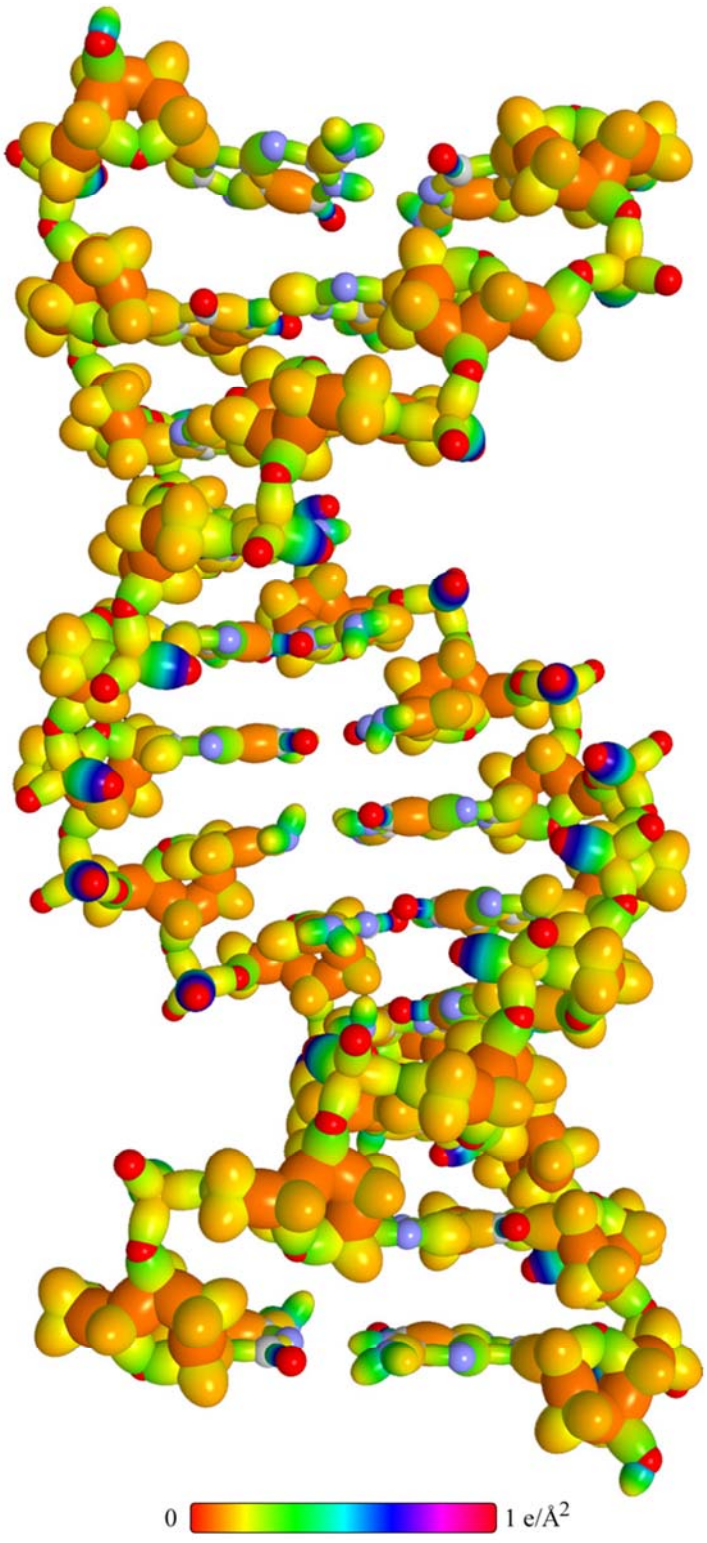


NATURE OF THE DIPOLE BOND: DIPOLE-DIPOLE, HYDROGEN, AND VAN DER WAALS BONDING

The boundless number and length of permutations of the functional groups can form a correspondingly infinite number of molecules. The intermolecular forces instill upon molecules their inherent properties such as state—being solid, liquid, or gas, the temperatures at which phase transitions occur, and the energy content change required to change the state. However, the types of bonding are relatively few even though the breadth of molecular compositions is infinite. Since all molecules comprise nuclei that behave on the scale of molecules as electrostatic point charges, and electrically charged electrons exist as charge and current densities that obey Maxwell's equations, the binding is determined by electrical and electrodynamics forces. These typically dominate over any magnetic forces since the latter is a relativistic effect of the former and is thus negligible as the norm. Thus, essentially all molecular bonding is Coulombic in nature. The extreme case involves ions, and ionic bonding between charged functional groups of molecules obeys the same physical principles as inorganic ions as given in the Nature of the Solid Ionic Bond of Alkali Hydrides and Halides section. Similarly, the charge-density distributions of negatively-charged electrons relative to the positively-charged nuclei of neutral molecules gives rise to Coulombic-based bonding that can be grouped into two main categories, bonding that comprises permanent dipole-dipole interactions further including an extreme case, hydrogen bonding, and bonding regarding reversible mutually induced dipole fields in near-neighbor molecules called van der Waals bonding.

The H bond is exemplary of the extreme of dipole-dipole interactions as the source of bond energy and rises from the extremely high dipole moments of H bound to F, O, or N as shown in the Bond and Dipole Moments section. The bond energies of these types of bonds are large due to the very high Coulombic energy associated with the dipole-dipole interaction between H-bonded molecules compared to those having much lower dipole moments. Still H-bond energies are typically small by the standards of covalent bonds. The differences are also reflected in the relative bond lengths. In water for example, the $O-H$ bond distance and energy are $2c' = 0.970 \pm .005\ \mathring{A}$ (Eq. (13.186)) and $E_D(H^{16}OH) = 5.1059\ eV$ (Eq. (13.222), respectively; whereas, those of the hydrogen bond of water are $2c'_{O\sim H} = 1.78\ \mathring{A}$ (Eq. (16.27) and $E_{vapor,0°C} = 0.233\ eV\ /\ H-bond$ (Eq. (16.57)), respectively. On the other end of the spectrum, van der Waals bonds are also Coulombic in nature and are between dipoles. However, the dipoles are mutually induced rather than permanent, and the mutual induction is typically small. Thus, the bond distances are on the order of angstroms and the energies in the 10's of meV's range. The bonding between molecules gives rise to condensed matter, and the classical theory of condensed matter based on these forms of bonding is treated next.

CONDENSED MATTER PHYSICS

Condensed matter comprises liquids and solids of atoms and molecules. It is shown *infra* that the geometrical parameters, energies, and properties of the latter can be solved using the same equations as those used to solve the geometrical parameters and component energies of the individual molecules as given in the Organic Molecular Functional Groups and Molecules section.

The structure and properties of liquids can be solved by first solving the unit cell of the corresponding condensed solid. The unit cell may be solved by first determining the packing that minimizes the lattice energy. In nature, there are a small, finite number of packing arrangements. The particular arrangement relates to the most efficient one giving the most objects packed into a given space with the size and shape limitations. The water molecule, for example, is small compared to the unit cell of ice; so, it will naturally assume a tetrahedral structure and hexagonal packing given the geometry of its electric dipoles with a partial positive on the H's and partial negative on the O. In general, a reiterative algorithm is used that optimizes the packing of the molecules and tests that packing against the unit cell parameters and lattice energy until an optimum is found. The lattice parameters can be verified by X-ray crystallography and neutron diffraction. The lattice energy can be measured using calorimetry; so, the model can be directly tested.

Bonding in neutral condensed solids and liquids arises from interactions between molecules wherein the molecules of the lattice have multipoles that give rise to corresponding Coulombic or magnetic interactions. Typically, the multipoles are electric or magnetic dipoles. Consider the former case. Since the separated partial charges that give rise to bond moments are equivalent to point charges centered on the bond nuclei as given in the Bond and Dipole Moments section, the maximum interaction energy between interacting species can be calculated using Coulomb's law with the corresponding partial monopole charges and separation distance. The energy from the interaction of the partial charges increases as the separation decreases, but concomitantly, the energy of a bond that may form between the interacting species increases as well. The equilibrium separation distance corresponds to the occurrence of the balance between the Coulombic potential energy of the interacting atoms and the energy of the bond whose formation involves the interacting atoms. Thus, the balance is at the energy threshold for the formation of a nascent bond that would replace the interacting partial charges while also destabilizing the standard bonds of the interacting molecules. Then, an optimal lattice structure corresponds to an energy minimum with an associated energy. The minimum energy structure corresponds to the highest density of interacting dipoles in their minimum energy state. A convenient method to calculate the lattice energy is to determine the electric or magnetic field in the material having an electric or magnetic polarization density, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic or magnetostatic form of Gauss' or Amperes' equation, respectively.

Once the a, b, and c parameters of the unit cell are solved from the energy (force) balance between the electric monopoles and the nascent bond energy, the unit cell is determined. Then, the unit cell can be proliferated to arbitrary scale to

render the solid. Typically, only one lattice parameter needs to be determined since the additional distances can be determined from geometrical relations based on the unit cell structure. The lattice energy may be calculated from the potential between dipoles using the cell parameters. The dielectric constant and other properties may also be calculated using Maxwell's equations and other first principles.

The structures of liquids can be modeled as linear combinations of unit cells comprising perturbations of the solid unit cell. In one approach, increasing disorder is added to the solid structure in the transition from solid to liquid to gas. Complete disorder or statistical gas behavior applies in the ideal gas limit. Thus, liquid states may be modeled by adding more cells with increasing loss of order of the solid unit cell as the temperature of the liquid is increased. The disorder is due to population of translational, rotational, and vibrational levels to match the internal energy at a given temperature. Consider thermodynamics. In principle, it is possible to classically calculate the fields over all space, the exact field interactions, and the position, trajectory, momentum, and energy of every particle of a material at each instance. Then, the material properties can be determined from these parameters. However, in practice, it is impossible computationally. For the same reason, simple underlying physical principles are applied to derive statistical properties for large ensembles of particles as given in the Statistical Mechanics section. The same statistical thermodynamic methods may be applied to modeling liquids and gases using the exact solutions of the individual molecules. Using the molecular geometrical parameters, charge distributions, and corresponding interactions as input, unit cells can be computed based on the solid unit cell. Working with increasing numbers of unit cells of increasing randomness and populating the unit cells based on appropriate statistical models such as Boltzmann statistics for increasing enthalpy input and temperature, accurate models of liquids are provided. The corresponding liquid properties can be solved from each liquid structure.

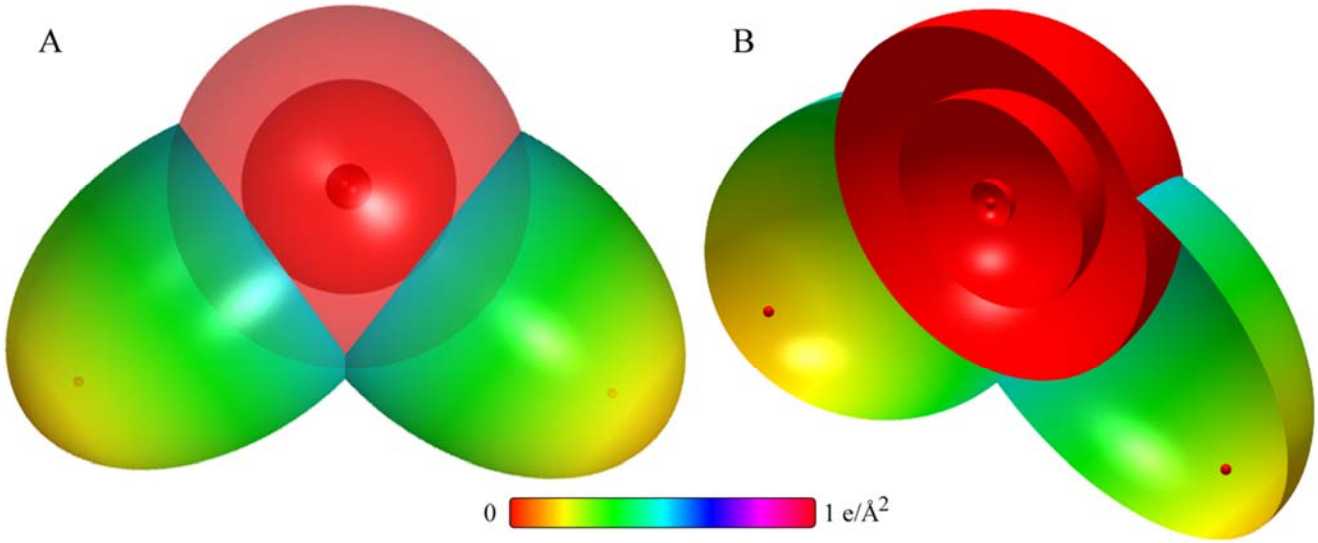
A preferred approach to solving the energy and geometric parameters of ice, considered next, is to solve the separation distance of the electric monopoles comprising a partial positive on each H and a partial negative charge on each O as the balance between the Coulombic attraction energy between the partial charges and the repulsion energy due to the formation of a nascent $H-O$ bond between the hydrogen-bonded atoms. The nascent bond substitutes for the hydrogen bond while also removing electron density and stability from the standard water molecule bonds. Thus, it offsets the Coulombic energy and establishes the equilibrium minimum approach distance of the interacting atoms of the water molecules. Then, using Gauss's law, the energy per water molecule is calculated as the dipole energy in the electric field of the lattice of electric dipoles.

GEOMETRICAL PARAMETERS AND ENERGIES OF THE HYDROGEN BOND OF H_2O IN THE ICE PHASE

The extraordinary properties of water are determined by hydrogen (H) bonds, designated by the dotted bond $O-H\cdots O$, each between a participating H of one water molecule and an O of another. The structure of each phase of water is then determined by the number of H bonds on average per water molecule. As shown in the Bond and Dipole Moments section, the $O-H$ bond has a bond moment μ of 1.51 D corresponding to a partial charge on each H of $+0.323e$ and a component of partial charge on each O per bond moment of $-0.323e$. The thermodynamic basis of the H bond is the minimization of the Coulombic energy between the H and O of the hydrogen bond, limited by the formation of a nascent bond between these atoms that destabilizes the initial $O-H$ bond. The sum of the torques and forces are zero at force balance to achieve a hexagonal crystal structure that is an energy minimum. The maximum electrostatic energy of the partial charges is calculated for the components along the H-bond axis. This energy is balanced by the total energy of the nascent bond that can form between the $H\cdots O$ atoms of the H bond. The bond length of the H bond, the internuclear distance between the H and O of the $H\cdots O$ bond, is calculated by a similar method as that used to determine the bond angle given in the Bond Angle of H_2O section.

The H_2O MO comprises a linear combination of two $O-H$-bond MOs. Each $O-H$-bond MO comprises the superposition of a H_2-type ellipsoidal MO and the $O2p_z$ AO or the $O2p_y$ AO with a relative H partial orbital contribution to the MO of 0.75; otherwise, the $O2p$ orbitals are the same as those of the oxygen atom. The solution of the geometrical parameters and component energies are given in the Water Molecule (H_2O) section and the color scale charge density of the H_2O MO is shown in Figure 16.7.

Figure 16.7. H_2O MO comprising the linear combination of two $O-H$ -bond MOs. Each $O-H$ -bond MO comprises the superposition of a H_2 -type ellipsoidal MO and the $O2p_z$ AO or the $O2p_y$ AO with a relative charge-density of 0.75 to 1.25; otherwise, the $O2p$ orbitals are the same as those of the oxygen atom. The internuclear axis of one $O-H$ bond is perpendicular to the bonding p_y orbital, and the internuclear axis of the other $O-H$ bond is perpendicular to the bonding p_z orbital. (A) Color scale, translucent view of the charge-density of the H_2O MO from the top. For each $O-H$ bond, the ellipsoidal surface of each H_2 -type ellipsoidal MO transitions to the $O2p$ AO. The $O2p$ shell, the $O2s$ shell, the $O1s$ shell, and the nuclei (red, not to scale) are shown. (B) Cut-away view showing the innermost $O1s$ shell, and moving radially, the $O2s$ shell, the $O2p$ shell, and the H_2 -type ellipsoidal MO that transitions to the $O2p$ AO for each $O-H$ bond. Bisector current not shown.



Rather than consider the possible bond between the two H atoms of the $O-H$ bonds in the determination of the bond angle, consider that the hydrogen bond may achieve a partial bond order or partial three-centered $O-H-O$ bond as given in the Bridging Bonds of Organoaluminum Hydrides ($Al-H-Al$ and $Al-C-Al$) and Bridging Bonds of Boranes ($B-H-B$ and $B-B-B$) sections, and the H can become mobile between water molecules corresponding to H exchange. Such exchange of $O\cdots H-O$ to $O-H\cdots O$ bonding would decrease the initial $O-H$ -bond strength since electron density would be shifted from the $O-H$ bonds to the $O\cdots H$ bond. Concomitantly, the Coulombic energy of the H bond would be eliminated. Thus, the equilibrium distance r_e or internuclear bond distance of $O\cdots H$ designated as $2c'_{O\cdots H}=r_e$ is determined by the condition that the total energy of the nascent H_2 -type ellipsoidal MO formed from the atoms of the $O\cdots H$ bond is equal to the maximum Coulombic energy between the partial charges of the H and O atoms of the H bond.

The $O-H$ bond moments superimpose at the central O. The minimum energy corresponds to the maximum separation of the δ^- of each bond moment on the O atom that occurs in space and time with π phase. The corresponding distance is the hypotenuse of the right triangle having the distance $2c'_{O\cdots H}$ between the H and O nuclei of the $H\cdots O$ bond as one side and the radius of the oxygen atom, $r_{O2p}=a_0$ (Eq. (10.162)), as the other. Then, the maximum Coulomb energy $E_{Coulomb}(H-bond)$ between the atoms of the $O\cdots H$ bond due to the two separated δ^-'s on the oxygen atom with the δ^+ centered on the nucleus of hydrogen is:

$$E_{Coulomb}(H-bond)=\frac{-2\delta^2e^2}{4\pi\varepsilon_0\sqrt{\left(2c'_{O\cdots H}\right)^2+\left(r_{O2p}\right)^2}} \tag{16.20}$$

Since each H bond is between two H_2O molecules and there are four H bonds per H_2O molecule, the Coulomb energy per H_2O $E_{Coulomb}(H_2O)$ is equivalent to two times $E_{Coulomb}(H-bond)$ (Eq. (16.20)):

$$E_{Coulomb}(H_2O)=\frac{-4\delta^2e^2}{4\pi\varepsilon_0\sqrt{\left(2c'_{O\cdots H}\right)^2+\left(r_{O2p}\right)^2}} \tag{16.21}$$

Eq. (16.21) is the energy to be equated to that of the nascent covalent bonds involving the atoms of the H bonds of the water molecule. Using Eq. (15.3), the internuclear distance of this bond, $2c'_{O\cdots H} = r_e$, in terms of the corresponding semimajor axis $a_{O\cdots H}$ is:

$$2c'_{O\cdots H} = 2\sqrt{\frac{a_{O\cdots H}a_0}{2C_1C_2}} \tag{16.22}$$

The length of the semiminor axis of the prolate spheroidal MO $b = c$ is given by:

$$b_{O\cdots H} = \sqrt{\left(a_{O\cdots H}\right)^2 - \left(c'_{O\cdots H}\right)^2} \tag{16.23}$$

And, the eccentricity, e, is:

$$e_{O\cdots H} = \frac{c'_{O\cdots H}}{a_{O\cdots H}} \tag{16.24}$$

The semimajor axis $a_{O\cdots H}$ of the $O\cdots H$ bond is determined using the general equation for determination of the bond angle between terminal atoms given by Eqs. (15.93) and (15.99) with Eqs. (15.46-15.47) except that the MO energy is matched to the Coulombic energy of the H bond (Eq. (16.21) with substitution of Eq. (15.3)) rather than being set equal to zero for zero interaction energy in the case of the bond-angle determination:

$$\frac{-4\delta^2e^2}{4\pi\varepsilon_0\sqrt{\left(2\sqrt{\frac{a_{O\cdots H}a_0}{2C_1C_2}}\right)^2 + \left(r_{O2p}\right)^2}} = \left[\begin{array}{l} \left(\begin{array}{l} -\frac{n_1e^2}{8\pi\varepsilon_0\sqrt{\frac{aa_0}{2C_1C_2}}}\left[c_1c_2\left(2-\frac{a_0}{a}\right)\ln\frac{a+\sqrt{\frac{aa_0}{2C_1C_2}}}{a-\sqrt{\frac{aa_0}{2C_1C_2}}} - 1\right] + E_T\left(AO/HO\right) \\ +E_T\left(atom-atom, msp^3.AO\right) \end{array}\right) \\ \left[1+\sqrt{\frac{2\hbar\sqrt{\frac{\frac{C_{1o}C_{2o}e^2}{4\pi\varepsilon_oR^3}}{m_e}}{m_ec^2}}\right] + n_1\frac{1}{2}\hbar\sqrt{\frac{\frac{c_1c_2e^2}{8\pi\varepsilon_oa^3} - \frac{e^2}{8\pi\varepsilon_o\left(a+\sqrt{\frac{aa_0}{2C_1C_2}}\right)^3}}{\mu}}\end{array}\right] \tag{16.25}$$

where n_1 is the number of equivalent bonds of the MO, c_1 is the fraction of the H_2-type ellipsoidal MO basis function, c_2 is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of each chemical bond, C_{1o} is the fraction of the H_2-type ellipsoidal MO basis function of the oscillatory transition state of a chemical bond of the group, and C_{2o} is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of the transition state of the chemical bond, $E_T\left(AO/HO\right)$ is the total energy comprising the difference of the energy $E\left(AO/HO\right)$ of at least one atomic or hybrid orbital to which the MO is energy matched and any energy component $\Delta E_{H_2MO}\left(AO/HO\right)$ due to the AO or HO's charge donation to the MO, $E_T\left(atom-atom, msp^3.AO\right)$ is the change in the energy of the AOs or HOs upon forming the bond, and μ is the reduced mass.

For the determination of the H-bond distance, the energy parameters are the same as those of water given in the Water Molecule $\left(H_2O\right)$ section except that any parameters due to matching AO's, $E_T\left(AO/HO\right)$ and $E_T\left(atom-atom, msp^3.AO\right)$, is zero since only the energies of the MO electrons to form the $O\cdots H$ MO are considered. The partial charge $\delta = q/e$ from Table 16.17 is 0.323, and the reduced mass is $\mu = \frac{16}{17}$. The parameters are summarized in Table 16.18 and Eq. (16.26).

Table 16.18. The energy parameters (eV) of the $O\cdots H$ functional group of the hydrogen bond of Type I ice.

Substitution of the parameters of Table 16.18, the internuclear distance $2c'_{O-H}$ given by Eq. (13.185), and R given by Eq. (16.23) and (16.22) into Eq. (16.25) gives:

$$\frac{-4(0.323)^2 e^2}{4\pi\varepsilon_0\sqrt{\left(2\sqrt{\frac{a_{O\cdots H}a_0}{2(0.75)}}\right)^2+\left(5.2917706\,X\,10^{-11}\ m\right)^2}}=\left\{\begin{array}{l}\left(\frac{-e^2}{4\pi\varepsilon_0\sqrt{\frac{a_{O\cdots H}a_0}{2(0.75)}}}\left(\left(\frac{3}{2}-\frac{3}{8}\frac{a_0}{a_{O\cdots H}}\right)\ln\frac{a_{O\cdots H}+\sqrt{\frac{a_{O\cdots H}a_0}{2(0.75)}}}{a_{O\cdots H}-\sqrt{\frac{a_{O\cdots H}a_0}{2(0.75)}}}-1\right)\right)\\ \left(1+2\sqrt{\frac{2\hbar\sqrt{\frac{\frac{3}{2}\frac{e^2}{4\pi\varepsilon_0\left(\sqrt{\left(a_{O\cdots H}\right)^2-\left(2\sqrt{\frac{a_{O\cdots H}a_0}{2(0.75)}}\right)^2}\right)^3}}{m_e}}{m_e c^2}}\right)\\ +2\left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{0.75e^2}{8\pi\varepsilon_o\left(a_{O\cdots H}\right)^3}-\frac{e^2}{8\pi\varepsilon_o\left(a+\sqrt{\frac{a_{O\cdots H}a_0}{2(0.75)}}\right)^3}}{\frac{16}{17}}}\end{array}\right\} \tag{16.26}$$

From the energy relationship given by Eq. (16.26) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $O\cdots H$ MO can be solved.

The most convenient way to solve Eq. (16.26) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{O\cdots H}=4.25343a_0=2.25082\,X\,10^{-10}\ m \tag{16.27}$$

The component energy parameters at this condition are given in Table 16.18. Substitution of Eq. (16.27) into Eq. (16.22) gives

$$c'_{O\cdots H}=1.68393a_0=8.91097\,X\,10^{-11}\ m \tag{16.28}$$

and internuclear distance of the H bond:

$$2c'_{O\cdots H}=3.36786a_0=1.78219\,X\,10^{-10}\ m=1.78219\ \text{Å} \tag{16.29}$$

The internuclear distance of the $O-H$ given by Eq. (13.185) is:

$$2c'=1.83601a_0=9.71574\,X\,10^{-11}\ m \tag{16.30}$$

The internuclear distance $2c'_{O\text{-}H}$ of the $O-H$ bond added to $2c'_{O\cdots H}$ gives the internuclear distance $2c'_{O\cdots HO}$ between the oxygen atoms of the group $O-H\cdots O$:

$$2c'_{O\cdots HO}=2c'_{O\cdots H}+2c'_{O\text{-}H} \tag{16.31}$$

Substitution of $2c'_{O\cdots H}$ (Eq. (16.29)) and $2c'_{O\text{-}H}$ (Eq. (13.185)) into Eq. (16.31) gives the nearest-neighbor separation, the internuclear distance $2c'_{O\cdots HO}$ between the oxygen atoms of the $O-H\cdots O$ bond in Type I ice:

$$2c'_{O\cdots HO}=2c'_{O\cdots H}+2c'_{O\text{-}H}=1.78219\,X\,10^{-10}\ m+9.71574\,X\,10^{-11}\ m=2.75377\,X\,10^{-10}\ m=2.75377\ \text{Å} \tag{16.32}$$

The experimental oxygen nearest-neighbor separation distance $2c'_{O\cdots HO}$ is [88]:

$$2c'_{O\cdots HO}=2.75\ \text{Å} \tag{16.33}$$

The experimental internuclear distance of the $O-H$ bond of H_2O is [89]:

$$2c'=9.70\pm.005\,X\,10^{-11}\ m \tag{16.34}$$

Using Eqs. (16.33) and (16.34), the experimental H bond distance $2c'_{O\cdots H}$ in Type I ice is [88, 89]:

$$2c'_{O\cdots H}=1.78\ \text{Å} \tag{16.35}$$

The other H-bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.27) and (16.28) into Eq. (16.23) gives:

$$b_{O\cdots H}=c_{O\cdots H}=3.90590a_0=2.06691\,X\,10^{-10}\ m \tag{16.36}$$

Substitution of Eqs. (16.27) and (16.28) into Eq. (16.24) gives:

$$e_{O\cdots H}=0.39590 \tag{16.37}$$

Since water is a hexagonal crystal system in common with the carbon allotrope diamond, the internuclear distance of the two terminal O atoms of a set of three H_2O's corresponding to the hexagonal lattice parameter a_l is calculated using the same approach as that given by Eqs. (17.1-17.3) using the law of cosines:

$$s_1^{\,2} + s_2^{\,2} - 2s_1 s_2 \text{cosine}\theta = s_3^{\,2} \tag{16.38}$$

where $s_3 = a_l$ is the hypotenuse of the isosceles triangle having equivalent sides of length equal to $2c'_{O\cdots HO}$. With the bond angle between three water molecules formed by the two corresponding H bonds given by $\theta_{\angle H_2O,H_2O,H_2O} = 109.5°$ [90] and $s_1 = s_2 = 2c'_{O\cdots HO}$ given by Eq. (16.32), the distance between the oxygen atoms of the terminal water molecules along the hypotenuse, $s_3 = 2c'_{H_2O\cdots H_2O} = a_l$, is:

$$a_l = 2c'_{H_2O\cdots H_2O} = \sqrt{2\left(2c'_{O\cdots HO}\right)^2\left(1-\cos ine(109.5°)\right)} = \sqrt{2\left(2.75377\ \text{Å}\right)^2\left(1-\cos ine(109.5°)\right)} = 4.49768\ \text{Å} \tag{16.39}$$

Due to the tetrahedral structure shown in Figure 16.8, four water molecules form a pyramidal structure with a central $H_2O(1)$ at the apex designated as on the z-axis, and the three other water molecules, $H_2O(n)$ $n = 2,3,4$, form the base in the xy-plane. As further shown in Figure 16.8, a fifth $H_2O(5)$ is positioned a distance $2c'_{O\cdots HO}$ along the z-axis. Twice the height along the z-axis from the base of the pyramid to the fifth H_2O comprises the Type I ice unit cell parameter c which is determined next using Eqs. (13.412-13.417).

Since any two $O-H\cdots O$ bonds having the internuclear distance $2c'_{O\cdots HO}$ between the oxygen atoms of Type I ice form an isosceles triangle having the hypotenuse a_l between the terminal oxygens, the distance $d_{origin-O}$ from the origin of the pyramidal base to the nucleus of a terminal oxygen atom is given by:

$$d_{origin-O} = \frac{a_l}{2\sin 60°} \tag{16.40}$$

Substitution of Eq. (16.39) into Eq. (16.40) gives

$$d_{origin-O} = 2.59674 a_0 \tag{16.41}$$

The height d_{height} along the z-axis of the pyramid from the origin to the O nucleus of $H_2O(1)$ is given by:

$$d_{height} = \sqrt{\left(2c'_{O\cdots HO}\right)^2 - \left(d_{origin-O}\right)^2} \tag{16.42}$$

Substitution of Eqs. (16.32) and (16.41) into Eq. (16.42) gives:

$$d_{height} = 0.91662 a_0 \tag{16.43}$$

The angle θ_v of each $O-H\cdots O$ bond from the z-axis is given by:

$$\theta_v = \tan^{-1}\left(\frac{d_{origin-O}}{d_{height}}\right) \tag{16.44}$$

Substitution of Eqs. (16.41) and (16.43) into Eq. (16.44) gives:

$$\theta_v = 70.56° \tag{16.45}$$

Using Eqs. (16.32) and (16.43), the hexagonal lattice parameter c_l for Type I ice given by twice the height along the z-axis from the base of the pyramid to the fifth water, $H_2O(5)$, is

$$c_l = 2\left(2c'_{O\cdots HO} + d_{height}\right) = 2\left(2.75377\ \text{Å} + 0.91662\ \text{Å}\right) = 7.34077\ \text{Å} \tag{16.46}$$

The experimental lattice parameters a_l and c_l for Type I ice are [90, 91]:

$$\begin{aligned} a_l &= 4.49\ \text{Å} \\ a_l &= 4.5212\ \text{Å} \end{aligned} \tag{16.47}$$

and [91, 92] :

$$\begin{aligned} c_l &= 7.31\ \text{Å} \\ c_l &= 7.3666\ \text{Å} \end{aligned} \tag{16.48}$$

The tetrahedral unit cell and the ideal hexagonal lattice structure of Type I ice are shown in Figures 16.8–16.10, using the color scale charge density of each water molecule.

Figure 16.8. Tetrahedral unit cell structure of Type I ice using the transparent color scale charge density of each H_2O MO comprising the linear combination of two $O-H$ -bond MOs. (A) Each dipole-dipole bond that is Coulombic in nature is depicted by connecting sticks. (B) Bond representation removed.

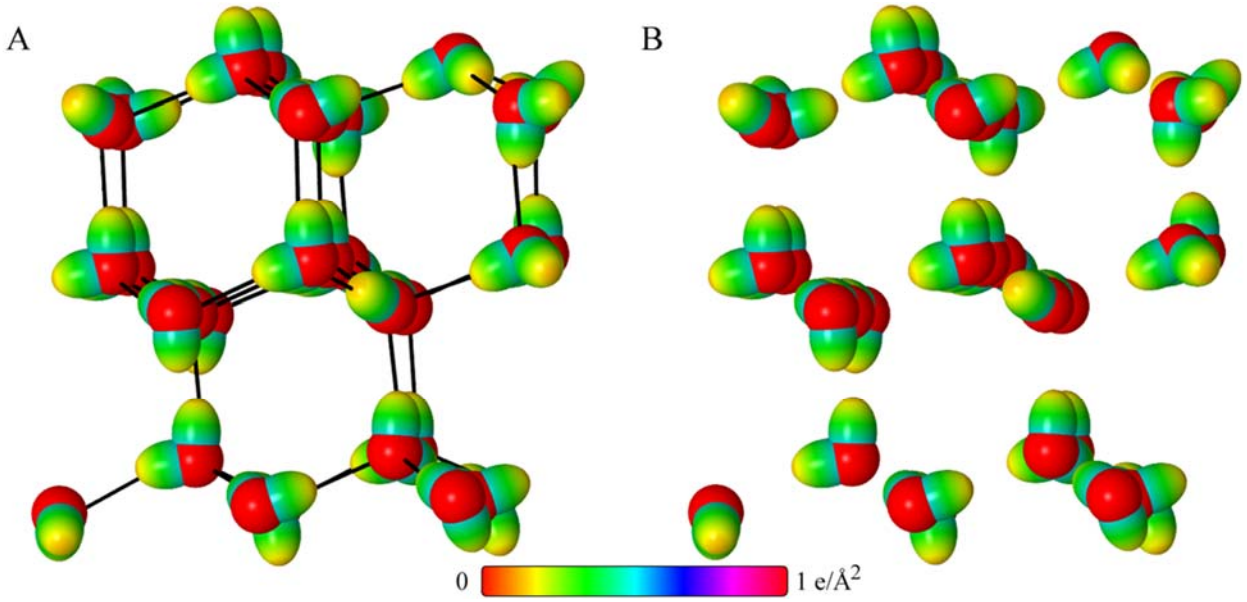

Figure 16.9. C-axis view of the ideal hexagonal lattice structure of Type I ice using the opaque color scale charge density of each H_2O MO comprising the linear combination of two $O-H$ -bond MOs. Each dipole-dipole bond that is Coulombic in nature is depicted by connecting sticks.

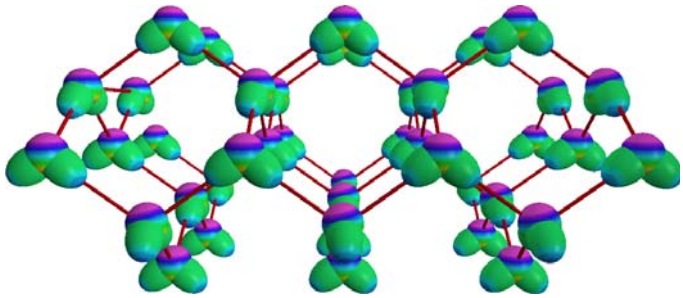

Figure 16.10. An off-angle view of the ideal hexagonal lattice structure of Type I ice using the opaque color scale charge density of each H_2O MO comprising the linear combination of two $O-H$ -bond MOs. Each dipole-dipole bond that is Coulombic in nature is depicted by connecting sticks.

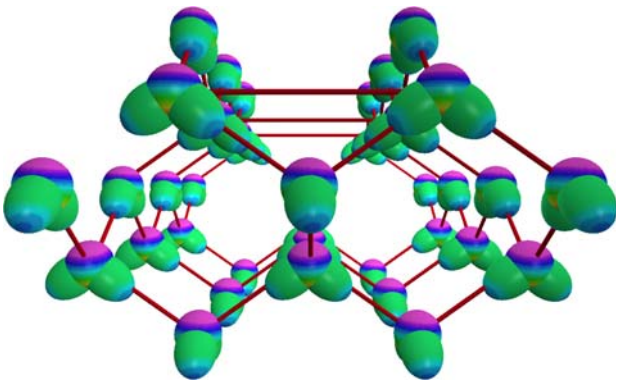

A convenient method to calculate the lattice energy is to determine the electric field in ice having an electric polarization density corresponding to the aligned molecular water dipoles moments, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic form of Gauss' equation. The electric field inside of a material having a uniform polarization density P_0 given by Eq. (6.3.3.15) of Haus and Melcher [93] is:

$$\mathbf{E}\left(H_2O\right)=\frac{P_0}{3\varepsilon_0}\left(-\cos\theta\mathbf{i}_r+\sin\theta\mathbf{i}_\theta\right) \tag{16.49}$$

The polarization density P_0 given by Eq. (6.3.3.3) of Haus and Melcher [93] is:

$$P_0=N\mu_{H_2O} \tag{16.50}$$

where μ_{H_2O} is the dipole moment of water and N is the number density of water dipoles given by the density ρ_{ice} divided by the molecular weight MW and multiplied by the Avogadro constant N_A:

$$N=\frac{\rho_{ice}}{MW}N_A \tag{16.51}$$

Substitution of Eqs. (16.50) and (16.51) into Eq. (16.49) gives:

$$\mathbf{E}\left(H_2O\right)=\frac{\mu_{H_2O}\dfrac{\rho_{ice}}{MW}N_A}{3\varepsilon_0}\left(-\cos\theta\mathbf{i}_r+\sin\theta\mathbf{i}_\theta\right) \tag{16.52}$$

The energy of forming the condensed phase is that of the alignment of the water dipoles each comprised of two $O-H$ component dipoles where the angular dependence along the z-axis in ice is unity, and this condition applies even in the case of the local order in water. The corresponding energy $U\left(H_2O\right)$ per water dipole due to the polarization electric field of the lattice of hexagonal dipoles is given by**:**

$$U\left(H_2O\right)=2\mu_{H_2O}\cdot\mathbf{E}\left(H_2O\right)=\frac{-2\left(\mu_{H_2O}\right)^2\dfrac{\rho_{ice}}{MW}N_A}{3\varepsilon_0} \tag{16.53}$$

Substitution of the density of ice $\rho=\dfrac{0.92\ g}{1\ X\ 10^{-6}\ m^3}$ [90], the $MW=18g/mole$, $N_A=6.0221415\ X\ 10^{23}\ molecules/mole$, and the water dipole moment given by Eq. (16.16) with the predicted and experimental hexagonal bond angle of ice, $\theta_{\angle H_2O}=109.5°$ [90]:

$$\mu_{H_2O}=2\left(1.51\right)\cos\left(109.5/2°\right)=5.79898\ X\ 10^{-30}C\cdot m \tag{16.54}$$

into Eq. (16.53) gives

$$\begin{aligned}U\left(H_2O\right)&=\frac{-2\left(5.79898\ X\ 10^{-30}C\cdot m\right)^2\dfrac{0.92\ g}{1\ X\ 10^{-6}\ m^3}6.0221415\ X\ 10^{23}\ molecules/mole}{18g/mole}\\&=-0.48643\ eV\ \left(-46.934\ kJ/mole\right)\end{aligned} \tag{16.55}$$

$U\left(H_2O\right)$ is also the negative of $E_{vapor,0°C}$, the energy of water initially at 0 °C or the energy of vaporization of water at 0 °C:

$$E_{vapor,0°C}=-U\left(H_2O\right)=0.48643\ eV\ \left(46.934\ kJ/mole\right) \tag{16.56}$$

The experimental energy of vaporization of water at 0 °C (Type I ice) is [94] :

$$E_{vapor,0°C}=45.054\ kJ/mole \tag{16.57}$$

The calculated results based on first principles and given analytical equations are summarized in Table 16.19.

Table 16.19. The calculated and experimental geometrical and energy parameters of the H bond of water of Type I ice.

Parameter	Calculated	Experimental	Ref. for Exp.
H Bond Length $2c'_{O\text{-}H}$	1.78219 Å	1.78 Å	88, 89
Nearest Neighbor Separation Distance $2c'_{O\text{-}HO}$	2.75377 Å	2.75 Å	88
H_2O Lattice Parameter a_l	4.49768 Å	4.49 Å 4.5212 Å	90 91
H_2O Lattice Parameter c_l	7.34077 Å	7.31 Å 7.3666 Å	92 91
Energy of Vaporization of Water at 0 °C	46.934 kJ/mole	45.054 kJ/mole	94

As the temperature increases, the corresponding molecular kinetic energy can excite a vibrational mode along the H bond axis. Concomitantly, the $O-H$ bond elongates and decreases in energy. As a consequence, the hydrogen bond achieves a partial bond order or partial three-centered $O-H-O$ bond, and the H can undergo exchange between water molecules. The time-average effect of exchange is to decrease the statistical equilibrium separation distance of water molecules. In competition with the separation-distance decreasing effect of exchange is the increasing effect due to collisional impact and recoil as a function of increasing temperature. The former effect dominates from the temperature of ice to 4°C at which point water assumes a maximum density. Thereafter, the momentum imparted with water-water collisions overwhelms the decrease due to exchange, and the molecular separation statistically increases with temperature until a totally gaseous state is achieved at atmospheric pressure at 100°C. Unit cells with increasing entropy can be derived from the ice unit cell by populating translational, rotational, and vibrational levels of molecules within the cells to match the internal energy at a given temperature. Using statistical mechanical models such as Boltzmann statistics to populate an increasing number of basis units cells of increasing disorder and based on the ice unit cell, the behavior of water as a function of temperature can be modeled over the range of states from ice to liquid to steam. The structure of each phase of water is then determined by the number of H bonds on average per water molecule. Based on the 10% energy change in the heat of vaporization in going from ice at 0°C to water at 100°C [94], the average number of H bonds per water molecule in boiling water is 3.6. The H bond distance is calculated next using the enthalpy to form steam from boiling water.

GEOMETRICAL PARAMETERS AND ENERGIES OF THE HYDROGEN BOND OF H_2O IN THE VAPOR PHASE

Two or more water molecules can interact along the $O\cdots H$ or H bond axis. In the gas phase, the maximum energy of interaction between water molecules of steam is equivalent to the negative of the heat of vaporization of water at the boiling point, 100°C; otherwise, water vapor would form the corresponding condensed state. For the determination of the H-bond distance, the energy parameters, partial charge, and reduced mass are the same as those of the water molecules of ice given in Eq. (16.26) except that the negative of the experimental $E_{vapor,100°C}=0.42137\,eV\ \left(40.657\,kJ/mole\right)$ [94] is equated to the nascent covalent bond energy. The parameters are summarized in Table 16.20 and Eq. (16.58).

Table 16.20. The energy parameters (eV) of the $O\cdots H$ functional group of the hydrogen bond of water vapor.

Parameters	$O\cdots H$ Group
δ	0.323
n_1	2
C_1	0.75
C_2	1
c_1	0.75
c_2	1
C_{1o}	1.5
C_{2o}	1
$V_e\ (eV)$	-15.20020

$\bar{E}_{Kvib}\ (eV)$	0.02033
$\bar{E}_{osc}\ (eV)$	0.008724
$E_{T(Group)}\ (eV)$	-0.42137

Substitution of the parameters of Table 16.20 and $-E_{vapor,0°C}$ (Eq. (16.57)) into Eq. (16.26) gives:

$$e\left(0.42137\ eV\right)=\left\{\left(\frac{-e^2}{4\pi\varepsilon_0\sqrt{\frac{a_{O\cdots H}a_0}{2(0.75)}}}\left(\left(\frac{3}{2}-\frac{3}{8}\frac{a_0}{a_{O\cdots H}}\right)\ln\frac{a_{O\cdots H}+\sqrt{\frac{a_{O\cdots H}a_0}{2(0.75)}}}{a_{O\cdots H}-\sqrt{\frac{a_{O\cdots H}a_0}{2(0.75)}}}-1\right)\right)\right\}$$
$$\left\{\left(1+2\sqrt{\frac{2\hbar\sqrt{\frac{\frac{3}{2}\frac{e^2}{4\pi\varepsilon_0\left(\sqrt{\left(a_{O\cdots H}\right)^2-\left(2\sqrt{\frac{a_{O\cdots H}a_0}{2(0.75)}}\right)^2}\right)^3}}{m_e}}{m_e c^2}}\right)\right.$$
$$\left.+2\left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{0.75e^2}{8\pi\varepsilon_o\left(a_{O\cdots H}\right)^3}-\frac{e^2}{8\pi\varepsilon_o\left(a_{O\cdots H}+\sqrt{\frac{a_{O\cdots H}a_0}{2(0.75)}}\right)^3}}{\frac{16}{17}}}\right\} \tag{16.58}$$

From the energy relationship given by Eq. (16.58) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $O\cdots H$ MO can be solved.

The most convenient way to solve Eq. (16.58) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{O\cdots H}=5.60039a_0=2.96360\,X\,10^{-10}\ m \tag{16.59}$$

The component energy parameters at this condition are given in Table 16.20. Substitution of Eq. (16.59) into Eq. (16.22) gives

$$c'_{O\cdots H}=1.93225a_0=1.02250\,X\,10^{-10}\ m \tag{16.60}$$

and internuclear distance of the H bond:

$$2c'_{O\cdots H}=3.86450a_0=2.04501\,X\,10^{-10}\ m \tag{16.61}$$

The experimental H bond distance $2c'_{O\cdots H}$ in the gas phase is [95]:

$$2c'_{O\cdots H}=2.02\,X\,10^{-10}\ m \tag{16.62}$$

and [96]

$$2c'_{O\cdots H}=2.05\,X\,10^{-10}\ m \tag{16.63}$$

The other H-bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.59) and (16.60) into Eq. (16.23) gives:

$$b_{O\cdots H}=c_{O\cdots H}=5.25650a_0=2.78162\,X\,10^{-10}\ m \tag{16.64}$$

Substitution of Eqs. (16.59) and (16.60) into Eq. (16.24) gives:

$$e_{O\cdots H}=0.34502 \tag{16.65}$$

Substitution of $2c'_{O\cdots H}$ (Eq. (16.61)) and $2c'_{O\cdots H}$ (Eq. (13.185)) into Eq. (16.31) gives the nearest neighbor separation, the internuclear distance $2c'_{O\cdots HO}$ between the oxygen atoms of the $O-H\cdots O$ bond of water vapor:

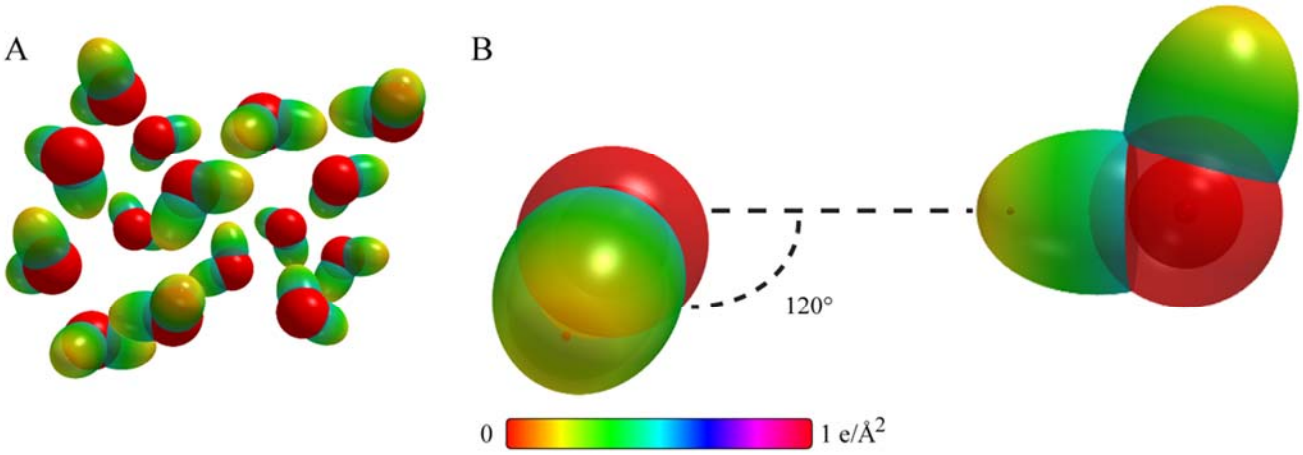
$$2c'_{O\cdots HO}=2c'_{O\cdots H}+2c'_{O-H}=2.04501\,X\,10^{-10}\ m+9.71574\,X\,10^{-11}\ m=3.01658\,X\,10^{-10}\ m=3.01658\,\text{Å} \tag{16.66}$$

Using Eqs. (16.31), (16.34), and (16.63), the experimental nearest neighbor separation $2c'_{O\cdots HO}$ is [89, 96]:

$$2c'_{O\cdots HO}=2c'_{O\cdots H}+2c'_{O-H}=2.05\,X\,10^{-10}\ m+9.70\,X\,10^{-11}\ m=3.02\,X\,10^{-10}\ m=3.02\,\text{Å} \tag{16.67}$$

H-bonded water vapor molecules in steam are shown in Figure 16.11 using the color scale charge density of each water molecule.

Figure 16.11. Structure of steam. (A). Ensemble of gaseous water molecules undergoing elastic hard-sphere collisions. (B). H-bonded water vapor molecules using the color scale charge density of each H_2O MO comprising the linear combination of two $O-H$ -bond MOs.



The calculated results based on first principles and given by analytical equations are summarized in Table 16.21.

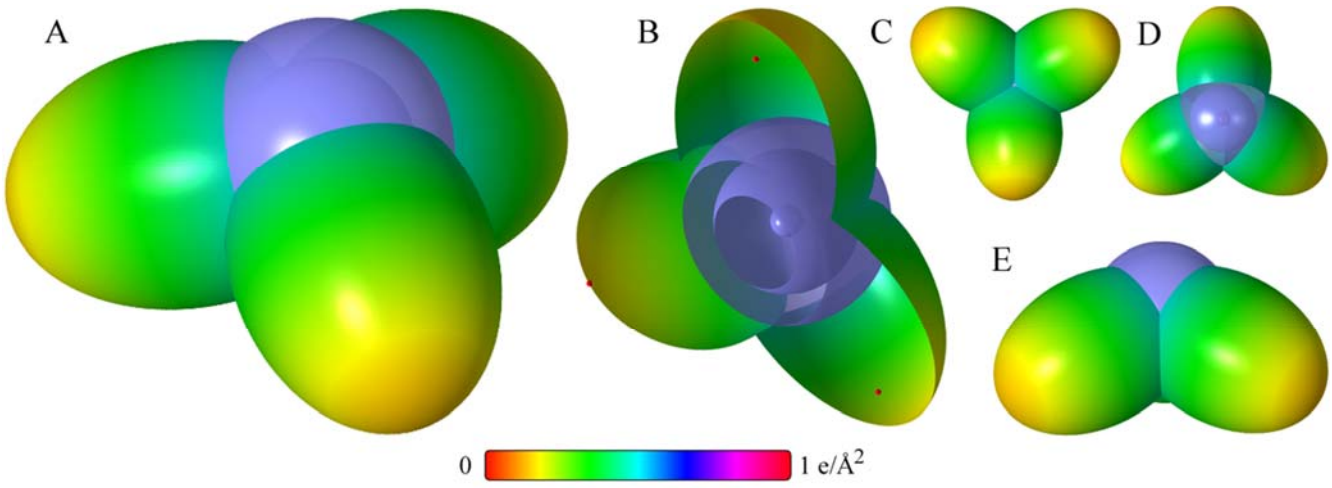
Table 16.21. The calculated and experimental geometrical and energy parameters of the H bond of steam.

Parameter	Calculated	Experimental	Ref. for Exp.
H Bond Length $2c'_{O\cdots H}$	2.04501 Å	2.02 Å 2.05 Å	95, 96
Nearest Neighbor Separation Distance $2c'_{O\cdots HO}$	3.01658 Å	3.02 Å	89, 96

GEOMETRICAL PARAMETERS AND ENERGIES OF THE HYDROGEN BOND OF H_2O AND NH_3

Similar to the water molecule, the ammonia molecule has a strong dipole moment along each of its $N-H$ -bonds. The NH_3 MO comprises the linear combination of three $N-H$ -bond MOs. Each $N-H$ -bond MO comprises the superposition of a H_2-type ellipsoidal MO and the $N2p_x$, $N2p_y$, or $N2p_z$ AO with a relative H partial orbital contribution to the MO of 0.75. The solution of the geometrical parameters and component energies are given in the Ammonia (NH_3) section, and the color scale charge density of the NH_3 MO is shown in Figure 16.12.

Figure 16.12. NH_3 MO comprising the linear combination of three $N-H$ -bonds. Each $N-H$ -bond MO comprises the superposition of a H_2-type ellipsoidal MO and the $N2p_x$, $N2p_y$, or $N2p_z$ AO. (A) Color scale, translucent view of the charge density of the NH_3 MO shown obliquely from the top. For each $N-H$ bond, the ellipsoidal surface of each H_2-type ellipsoidal MO transitions to a $N2p$ AO. The $N2p$ shell, the $N2s$ shell, the $N1s$ shell, and the nuclei (red, not to scale) are shown. (B) Off-center cut-away view showing the complete inner most $N1s$ shell, and moving radially, the cross section of the $N2s$ shell, the $N2p$ shell, and the H_2-type ellipsoidal MO that transitions to a $N2p$ AO for each $N-H$ bond. (C)-(E) Color scale, side-on, top, and bottom translucent views of the charge density of the NH_3 MO, respectively.



Due to the interacting dipoles, hydrogen bonds also form between the nitrogen of ammonia and the hydrogen of water molecules. Water hydrogen bonds to ammonia molecules by interaction along the $N\cdots HO$ or H bond axis. As shown in the Bond and Dipole Moments section, each $N-H$ bond of ammonia has a bond moment μ of 1.30 D corresponding to a N component of partial charge of $-0.262e$, and the $O-H$ bond has a bond moment μ of 1.51 D corresponding to a H partial charge of $+0.323e$. The thermodynamic basis of the H bond is the minimization of the Coulombic energy between the hydrogen bonded H of H_2O and N of ammonia, limited by the formation of a nascent $N-H$ bond between these atoms that destabilizes the initial $O-H$ bond of the water molecule partner. As in the case of ice, the maximum electrostatic energy of the partial charges is calculated for the components along the H-bond axis. This energy is balanced by the total energy of the nascent bond that can form between the $N\cdots H$ atoms of the H bond. The bond length of the H bond, the internuclear distance between the N and H of the $N\cdots H$ bond, is calculated using Eq. (16.25) by a similar method as that used to calculate the $O\cdots H$ bond distance of ice. According to the method given in the Geometrical Parameters and Energies of the Hydrogen Bond of H_2O section, the equilibrium distance r_e or internuclear bond distance of $N\cdots H$ designated as $2c'_{N\cdots H}=r_e$ is determined by the condition that the total energy of the nascent H_2-type ellipsoidal MO formed from the atoms of the $N\cdots H$ bond is equal to the maximum Coulombic energy between the partial charges of the N and H atoms of the H bond.

The maximum Coulumbic energy corresponds to the minimum separation distance of N and H atoms corresponding to the alignment along the $N\cdots H$ bond axis. The corresponding distance from the δ^+ of the H_2O H and the NH_3 N is the

distance $2c'_{N\cdots H}$ between the N and H nuclei of the $N\cdots H$ bond. Then, the maximum Coulomb energy $E_{Coulomb}(H-bond)$ between the atoms of the $N\cdots H$ bond due to the δ^- on the nitrogen atom with the δ^+ centered on the nucleus of hydrogen is:

$$E_{Coulomb}(H-bond)=\frac{-\delta_N^-\delta_H^+e^2}{4\pi\varepsilon_0 2c'_{N\cdots H}} \tag{16.68}$$

Eq. (16.68) is the energy to be equated to that of the nascent bonds involving the atoms of the H bond.

For the determination of the H-bond distance, the energy parameters of the nascent $N-H$ bond are the same as those of ammonia given in the Ammonia (NH_3) section except that any parameter due to matching AO's, $E_T(AO/HO)$ and $E_T(atom-atom,msp^3.AO)$, is zero since only the energies of the MO electrons to form the $N\cdots H$ MO are considered. The energy of Eq. (16.68) is multiplied by three to match the total energy of the three $N-H$ bond MOs of ammonia. The partial charges $\delta=q/e$ from Table 16.17 are –0.262 and +0.323, and the reduced mass is $\mu=\frac{14}{15}$. The parameters are summarized in Table 16.22 and Eq. (16.69).

Table 16.22. The energy parameters (eV) of the $N\cdots H$ functional group of the hydrogen bond of the ammonia-water molecular dimer.

Parameters	$N\cdots H$ Group
δ_N^-	0.262
δ_H^+	0.323
n_1	3
C_1	0.75
C_2	0.93613
c_1	0.75
c_2	1
C_{1o}	1.5
C_{2o}	1
$V_e\ (eV)$	-23.60741
$V_p\ (eV)$	20.75035
$T\ (eV)$	2.17246
$V_m\ (eV)$	-1.08623
$E_{(AO/HO)}\ (eV)$	0
$\Delta E_{H_2MO(AO/HO)}\ (eV)$	0
$E_{T(AO/HO)}\ (eV)$	0
$E_{T(H_2MO)}\ (eV)$	-1.77083
$E_T\left(atom-atom, msp^3.AO\right)\ (eV)$	0
$E_{T(MO)}\ (eV)$	-1.77083
$\omega\ \left(10^{15}\ rad/s\right)$	4.44215
$E_K\ (eV)$	2.92390
$\bar{E}_D\ (eV)$	-0.00599
$\bar{E}_{Kvib}\ (eV)$	0.021843
$\bar{E}_{osc}\ (eV)$	0.00493
$E_{T(Group)}\ (eV)$	1.75603
$E_{T(Group)}\ (eV)$ per $N-H$	0.58534

Substitution of the parameters of Table 16.22 into Eq. (16.25) with $R=a_{N\cdots H}$ gives:

$$\frac{-3(0.262)(0.323)e^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{N\cdots H}a_0}{2(0.75)(0.93613)}}\right)}=\left\{\begin{array}{l}\left(\frac{-3e^2}{8\pi\varepsilon_0\sqrt{\frac{a_{N\cdots H}a_0}{2(0.75)(0.93613)}}}\left(\left(\frac{3}{2}-\frac{3}{8}\frac{a_0}{a_{N\cdots H}}\right)\ln\frac{a_{N\cdots H}+\sqrt{\frac{a_{N\cdots H}a_0}{2(0.75)(0.93613)}}}{a_{N\cdots H}-\sqrt{\frac{a_{N\cdots H}a_0}{2(0.75)(0.93613)}}}-1\right)\right)\\ \left(1+3\sqrt{\frac{2\hbar\sqrt{\frac{\frac{3}{2}\frac{e^2}{4\pi\varepsilon_0\left(\sqrt{(a_{N\cdots H})^2-\left(2\sqrt{\frac{a_{N\cdots H}a_0}{2(0.75)}}\right)^2}\right)^3}}{m_e}}{m_ec^2}}\right)\\ +3\left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{0.75e^2}{8\pi\varepsilon_o(a_{N\cdots H})^3}-\frac{e^2}{8\pi\varepsilon_o\left(a_{N\cdots H}+\sqrt{\frac{a_{N\cdots H}a_0}{2(0.75)(0.93613)}}\right)^3}}{\frac{14}{15}}}\end{array}\right\} \tag{16.69}$$

From the energy relationship given by Eq. (16.69) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $N\cdots H$ MO can be solved.

The most convenient way to solve Eq. (16.69) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{N\cdots H}=5.43333a_0=2.87519\,X\,10^{-10}\ m \tag{16.70}$$

The component energy parameters at this condition are given in Table 16.22. Substitution of Eq. (16.70) into Eq. (16.22) gives

$$c'_{N\cdots H}=1.96707a_0=1.04093\,X\,10^{-10}\ m \tag{16.71}$$

and internuclear distance of the H bond:

$$2c'_{N\cdots H}=3.93414a_0=2.08186\,X\,10^{-10}\ m=2.08186\,\text{Å} \tag{16.72}$$

The experimental H bond distance $2c'_{N\cdots H}$ in the gas phase is [96, 97]:

$$2c'_{N\cdots HO}=2.02\,X\,10^{-10}\ m \tag{16.73}$$

The other H-bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.70) and (16.71) into Eq. (16.23) gives

$$b_{N\cdots H}=c_{N\cdots H}=5.06475a_0=2.68015\,X\,10^{-10}\ m \tag{16.74}$$

Substitution of Eqs. (16.70) and (16.71) into Eq. (16.24) gives:

$$e_{N\cdots H}=0.36204 \tag{16.75}$$

The addition of $2c'_{N\cdots H}$ (Eq. (16.72)) and $2c'_{O\cdots H}$ (Eq. (13.185)) gives the nearest neighbor separation, the internuclear distance $2c'_{N\cdots HO}$ between the nitrogen and oxygen atoms of the $N\cdots H-O$ bond of the ammonia-water molecular dimer:

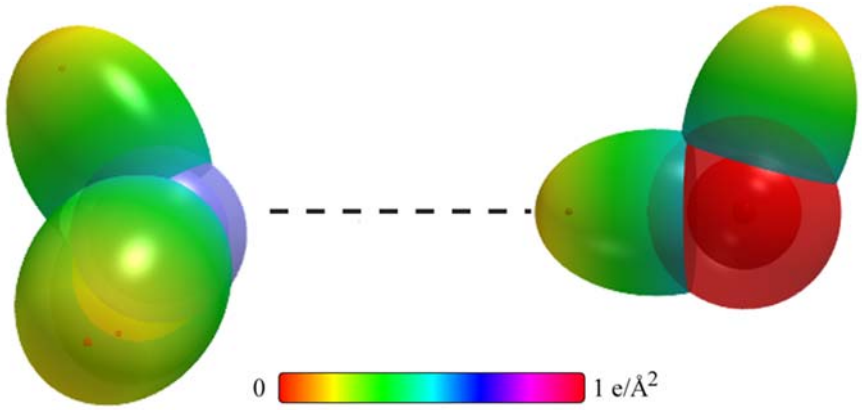
$$\begin{aligned}2c'_{N\cdots HO}&=2c'_{N\cdots H}+2c'_{O\cdots H}=2.08186\,X\,10^{-10}\ m+9.71574\,X\,10^{-11}\ m\\&=3.05343\,X\,10^{-10}\ m=3.05343\,\text{Å}\end{aligned} \tag{16.76}$$

The addition of the experimental $2c'_{N\cdots H}$ (Eq. (16.73)) and $2c'_{O\cdots H}$ (Eq. (13.185)) gives the experimental nearest neighbor separation $2c'_{N\cdots HO}$ [96, 89]:

$$\begin{aligned}2c'_{N\cdots HO}&=2c'_{N\cdots H}+2c'_{O\cdots H}=2.02\,X\,10^{-10}\ m+9.70\,X\,10^{-11}\ m\\&=2.99\,X\,10^{-10}\ m=2.99\,\text{Å}\end{aligned} \tag{16.77}$$

H-bonded ammonia-water molecular dimer is shown in Figure 16.13 using the color scale charge density of each molecule.

Figure 16.13. Structure of the $H_3N\cdots H-OH$ H bond. The H-bonded ammonia-water vapor molecular dimer using the color scale charge density of each NH_3 and H_2O MO comprising the linear combination of three $N-H$ and two $O-H$ -bond MOs, respectively.



The energy of forming the dimer in the gas phase is that of the alignment of the ammonia dipole moment in the electric field of the $H-O$ water dipole. Using $\mu_{H_3N}=1.467\ D=4.89196\ X\ 10^{-30}C\cdot m$ Eq. (16.18), $\mu_{H-O,H_2O}=1.51\ D=5.02385\ X\ 10^{-30}C\cdot m$ (Table 16.17), and the $N\cdots H$ distance, $2c'_{N\cdots H}=2.08186\ X\ 10^{-10}\ m$ (Eq. (16.72)), the $N\cdots H$ bond dissociation energy $E_D(N\cdots H)$ of the ammonia-water molecular dimer is:

$$E_D(N\cdots H)=\mu_{H_3N}\cdot\frac{2\mu_{H-O,H_2O}}{4\pi\varepsilon_0\left(2c'_{N\cdots H}\right)^3}$$
$$=\frac{\left(4.89196\ X\ 10^{-30}C\cdot m\right)\left(5.02385\ X\ 10^{-30}C\cdot m\right)}{4\pi\varepsilon_0\left(2.08186\ X\ 10^{-10}\ m\right)^2}=29.48\ kJ \tag{16.78}$$

The experimental $N\cdots H$ bond dissociation energy between amino N and hydroxyl H is approximately [98] :

$$E_D(N\cdots H)=29\ kJ \tag{16.79}$$

The calculated results based on first principles and given by analytical equations are summarized in Table 16.23.

Table 16.23. The calculated and experimental geometrical and energy parameters of the H-bonded ammonia-water vapor molecular dimer.

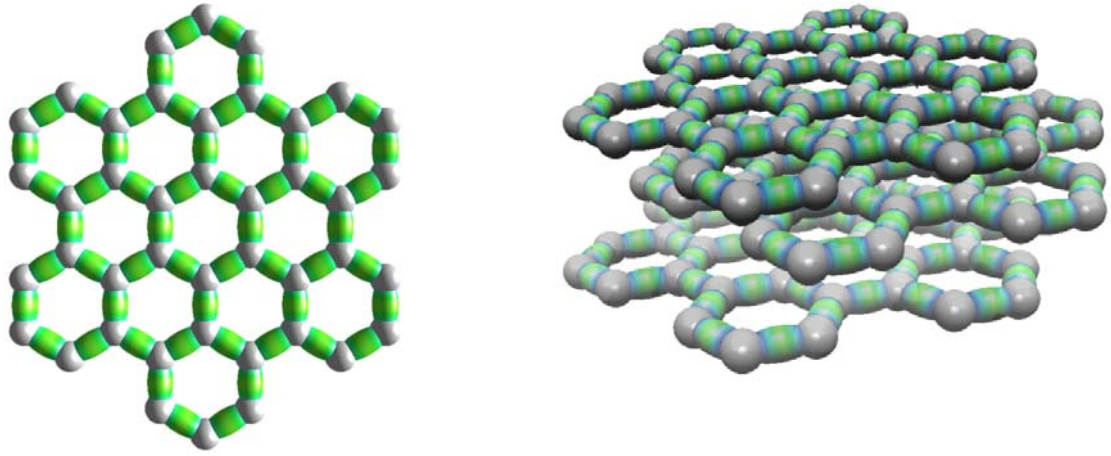
Parameter	Calculated	Experimental	Ref. for Exp.
H Bond Length $2c'_{N\cdots H}$	2.08186 Å	2.02 Å	96, 97
Nearest Neighbor Separation Distance $2c'_{N\cdots HO}$	3.05343 Å	2.99 Å	96, 89
$N\cdots H$ Bond Dissociation Energy	29.48 kJ/mole	29 kJ/mole	98

GEOMETRICAL PARAMETERS DUE TO THE INTERPLANE VAN DER WAALS COHESIVE ENERGY OF GRAPHITE

Eq. (16.25) can be applied to other solids such as graphite. Graphite is an allotrope of carbon that comprises planar sheets of covalently bound carbon atoms arranged in hexagonal aromatic rings of a macromolecule of indefinite size. The structure of graphite is shown in Figures 16.14A and B. The structure shown in Figure 16.14 has been confirmed directly by TEM imaging, and the Pi cloud predicted by quantum mechanics has been dispatched [99].

Figure 16.14. The structure of graphite. (A) Single plane of macromolecule of indefinite size. (B) Layers of graphitic planes.

(A) **(B)**



As given in the Graphite section, the structure of the indefinite network of aromatic hexagons of a sheet of graphite is solved using a linear combination of aromatic $C\overset{3e}{=}C$ aromatic bonds comprising $(0.75)(4)=3$ electrons according to Eq. (15.161). In graphite, the minimum energy structure with equivalent carbon atoms wherein each carbon forms bonds with three other such carbons requires a redistribution of charge within an aromatic system of bonds. Considering that each carbon contributes four bonding electrons, the sum of electrons of graphite at a vertex-atom comprises four from the vertex atom plus two from each of the two atoms bonded to the vertex atom where the latter also contribute two each to the juxtaposed bond. These eight electrons are distributed equivalently over the three bonds of the group such that the electron number assignable to each bond is $\frac{8}{3}$. Thus, the $C\overset{8/3e}{=}C$ functional group of graphite comprises the aromatic bond with the exception that the electron-number per bond is $\frac{8}{3}$. The sheets, in turn, are bound together by weaker intermolecular van der Waals forces. The geometrical and energy parameters of graphite are calculated using Eq. (16.25) with the van der Waals energy equated to the nascent bond energy.

The van der Waals energy is due to mutually induced nonpermanent dipoles in near-neighbor bonds. Albeit, the $C\overset{8/3e}{=}C$ functional group is symmetrical such that it lacks a permanent dipole moment, a reversible dipole can be induced upon van der Waals bonding. The parameters of the $C\overset{8/3e}{=}C$ functional group are the same as those of the aromatic $C\overset{3e}{=}C$ functional group, the basis functional group of aromatics, except that the bond order is 8/3 (e.g. $2c'_{C\overset{8/3e}{=}C}=2c'_{C\overset{3e}{=}C}$). Using Eq. (16.15) wherein C_2 of Eq. (15.51) for the aromatic $C\overset{3e}{=}C$-bond MO is $C_2\left(aromaticC2sp^3HO\right)=c_2\left(aromaticC2sp^3HO\right)=0.85252$ (Eq. (15.162)) and $E_{Coulomb}\left(C_{benzene},2sp^3\right)$ is 15.95955 eV (Eq. (14.245)), $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (14.143)) and $2c'=1.39140\ X\ 10^{-10}\ m$ (Table 15.214), the van der Waals dipole of graphite is given in Table 16.24.

Table 16.24. The parameters and van der Waals dipole bond moment of the $C\overset{8/3e}{=}C$ functional group of graphite.

Functional Group	n_1	$(c_1)c_2$	(C_1) C_2	$E_B(valence)$	$E_A(valence)$	$\frac{q}{e}$	Bond Length $2c'$ $(\AA)$	Bond Moment μ (D)

$C \overset{8/3e}{=} C$	$\frac{8}{3}$	0.85252	1	14.82575	15.95955	0.36101	1.3914	2.41270

The interaction between a dipole in one plane with the nearest neighbor in another plane is zero in the case that the aromatic rings of one layer are aligned such that they would superimpose as the interlayer separation goes to zero. But, the energy of interaction is nonzero when one plane is translated relative to a neighboring plane. A minimum equal-energy is achieved throughout the graphite structure when each layer is displaced by $2c'_{C\overset{3e}{=}C}$, the bond length of $C \overset{8/3e}{=} C$, along an intra-planar C_2 axis relative to the next as shown in Figure 16.14B. Then, a pair of dipoles exists for each dipole of a given plane with one dipole above and one below in neighboring planes such that all planes can be equivalently bound by van der Waals forces. In this case, the distance $r_{\mu_1\cdots\mu_2}$ between dipole μ_1 in one plane and its nearest neighbor μ_2 above or below on a neighboring and $2c'_{C\overset{3e}{=}C}$-displaced plane is**:**

$$r_{\mu_1\cdots\mu_2} = \sqrt{\left(2c'_{C\overset{3e}{=}C}\right)^2 + \left(2c'_{C\cdots C}\right)^2} \tag{16.80}$$

where $2c'_{C\cdots C}$ is the interplane distance. The alignment angle $\theta_{\mu_1\cdots\mu_2}$ between the dipoles is**:**

$$\theta_{\mu_1\cdots\mu_2} = \sin^{-1}\frac{2c'_{C\cdots C}}{r_{\mu_1\cdots\mu_2}} = \sin^{-1}\frac{2c'_{C\cdots C}}{\sqrt{\left(2c'_{C\overset{3e}{=}C}\right)^2 + \left(2c'_{C\cdots C}\right)^2}} \tag{16.81}$$

The van der Waals energy is the potential energy between interacting neighboring pairs of $C \overset{8/3e}{=} C$ induced dipoles. Using Eqs. (16.80-16.81), $\mu_{C\overset{8/3e}{=}C} = 2.41270\ D = 8.04790\ X\ 10^{-30} C\cdot m$ (Table 16.24), and the $C \overset{8/3e}{=} C$ distance, $2c'_{C\overset{8/3e}{=}C} = 1.39140\ X\ 10^{-10}\ m$ (Table 15.214), the van der Waals energy of graphite between two planes at a vertex atom is**:**

$$E_{van\ der\ Waals}(graphite) = (3)\frac{2\left(\mu_{C\overset{8/3e}{=}C}\right)^2}{4\pi\varepsilon_0\left(r_{\mu_1\cdots\mu_2}\right)^3}\cos\theta_{\mu_1\cdots\mu_2}$$

$$= \left(\frac{6\left(8.04790\ X\ 10^{-30} C\cdot m\right)^2}{4\pi\varepsilon_0\left(\left(1.39140\ X\ 10^{-10}\ m\right)^2 + \left(2\sqrt{\frac{a_{C\cdots C}a_0}{2C_1C_2}}\right)^2\right)^{1.5}}\right)\left(\cos\sin^{-1}\frac{2\sqrt{\frac{a_{C\cdots C}a_0}{2C_1C_2}}}{\sqrt{\left(1.39140\ X\ 10^{-10}\ m\right)^2 + \left(2\sqrt{\frac{a_{C\cdots C}a_0}{2C_1C_2}}\right)^2}}\right) \tag{16.82}$$

where there are three bonds at each vertex atom.

The graphite inter-plane distance of 3.5Å [100] is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.82)) between dipoles of two neighboring planes equated to the nascent bond energy. The energy matching parameter c_2 is the same that of the graphite sheet corresponding to the aromatic carbons as given in the Graphite section, and the reduced mass is $\mu = 6$. The parameters are summarized in Table 16.25 and Eq. (16.83).

Table 16.25. The energy parameters (eV) of the graphite interplanar functional group ($C_{aromatic}\cdots C_{aromatic}$).

Parameters	$C_{aromatic}\cdots C_{aromatic}$ Group
n_1	1
C_1	0.5
C_2	1

$E_{T(Group)}\ (eV)$	-0.14905

Substitution of the parameters of Table 16.25 and the interlayer cohesive energy of graphite (Eq. (16.82)) into Eq. (16.25) with $R=a_{C\text{-}C}$ gives:

$$\frac{-6\left(8.04790\,X\,10^{-30}\,C\cdot m\right)^2}{4\pi\varepsilon_0\left(\left(1.39140\,X\,10^{-10}\,m\right)^2+\left(2\sqrt{\frac{a_{C\cdots C}a_0}{2(0.5)}}\right)^2\right)^{1.5}}\cos\sin^{-1}\frac{2\sqrt{\frac{a_{C\cdots C}a_0}{2(0.5)}}}{\sqrt{\left(1.39140\,X\,10^{-10}\,m\right)^2+\left(2\sqrt{\frac{a_{C\cdots C}a_0}{2(0.5)}}\right)^2}}$$

$$=\left\{\left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{a_{C\cdots C}a_0}{2(0.5)}}}\left((0.85252)\left(2-\frac{1}{2}\frac{a_0}{a_{C\cdots C}}\right)\ln\frac{a+\sqrt{\frac{a_{C\cdots C}a_0}{2(0.5)}}}{a-\sqrt{\frac{a_{C\cdots C}a_0}{2(0.5)}}}-1\right)\right)\left(1+2\sqrt{\frac{2\hbar\sqrt{\frac{(0.5)\frac{e^2}{4\pi\varepsilon_o\left(a_{C\cdots C}\right)^3}}{m_e}}}{m_ec^2}}\right)\right.$$
$$\left.+\left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{(0.85252)e^2}{8\pi\varepsilon_o\left(a_{C\cdots C}\right)^3}-\frac{e^2}{8\pi\varepsilon_o\left(a_{C\cdots C}+\sqrt{\frac{a_{C\cdots C}a_0}{2(0.5)}}\right)^3}}{6}}\right\} \tag{16.83}$$

From the energy relationship given by Eq. (16.83) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $C\cdots C$ MO can be solved.

The most convenient way to solve Eq. (16.83) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{C\cdots C}=11.00740a_0=5.82486\,X\,10^{-10}\,m \tag{16.84}$$

The component energy parameters at this condition are given in Table 16.25. Substitution of Eq. (16.84) into Eq. (16.22) gives:

$$c'_{C\cdots C}=3.31774a_0=1.75567\,X\,10^{-10}\,m \tag{16.85}$$

and internuclear distance of the graphite interplane bond at vacuum ambient pressure:

$$2c'_{C\cdots C}=6.63548a_0=3.51134\,X\,10^{-10}\,m=3.51134\,\text{Å} \tag{16.86}$$

The experimental graphite interplane distance $2c'_{C\cdots C}$ is [100]:

$$2c'_{C\cdots C}=3.5\,X\,10^{-10}\,m=3.5\,\text{Å} \tag{16.87}$$

The other interplane bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.84) and (16.85) into Eq. (16.23) gives:

$$b_{C\cdots C}=c_{C\cdots C}=10.49550a_0=5.55398\,X\,10^{-10}\,m \tag{16.88}$$

Substitution of Eqs. (16.84) and (16.85) into Eq. (16.25) gives:

$$e_{C\cdots C}=0.30141 \tag{16.89}$$

Using Eqs. (16.80) and (16.86), the distance $r_{\mu_1\cdots\mu_2}$ between dipole μ_1 on one plane and its nearest neighbor μ_2 above or below on a juxtaposed and $2c'_{\substack{3e\\C=C}}$-displaced plane is:

$$r_{\mu_1\cdots\mu_2}=3.77697\,X\,10^{-10}\,m \tag{16.90}$$

Using Eqs. (16.81) and (16.86), the alignment angle $\theta_{\mu_1\cdots\mu_2}$ between the dipoles is**:**

$$\theta_{\mu_1\cdots\mu_2}=68.38365\,^\circ \tag{16.91}$$

Using Eqs. (16.82) and (16.90-91), the van der Waals energy per carbon atom is:

$$E_{van\ der\ Waals}\left(graphite/C\right)=0.04968\,eV \tag{16.92}$$

The experimental van der Waals energy per carbon atom is [101]:

$$E_{van\ der\ Waals}\left(graphite/C\right)=0.052\,eV \tag{16.93}$$

The calculated results based on first principles and given by analytical equations are summarized in Table 16.26.

Table 16.26. The calculated and experimental geometrical parameters and interplane van der Waals cohesive energy of graphite.

Parameter	Calculated	Experimental	Ref. for Exp.
Graphite Interplane Distance $2c'_{C-C}$	3.51134 Å	3.5 Å	100
van der Waals Energy per Carbon Atom	0.04968 eV	0.052 eV	101

Graphite has a high cohesive energy due to its significant van der Waals dipole bond moment of 2.41270D. Other species such as atoms and molecules having mirror symmetry and consequently no permanent dipole moment also form reversible van der Waals dipole bond moments. Different phases can be achieved according to the extent of the van der Waals dipole bonding as the internal energy as a function of temperature and pressure changes analogously to the H-bonded system water that can exist as ice, water, and steam. Thus, the factors in the van der Waals bonding can give rise to numerous material behaviors. In the case of atoms such as noble gas atoms and certain diatomic molecules such as hydrogen, the moments, their interaction energies, and the corresponding nascent bond energies are much smaller. Thus, except at cryogenic temperatures, these elements exist as gases, and even at temperatures approaching absolute zero, solidification of helium has not been achieved in the absence of high pressure. This is due to the nature of the induced dipoles and van der Waals phenomena in helium. Since this system is a good example of van der Waals forces in atoms, it will be treated next.

GEOMETRICAL PARAMETERS AND ENERGIES DUE TO THE INTERATOMIC VAN DER WAALS COHESIVE ENERGY OF LIQUID HELIUM

Noble gases such as helium are typically gaseous and comprised of non-interacting atoms having no electric or magnetic multipoles. But, at very low temperatures it is possible to form diffuse diatomic molecules, or alternatively, these gases may be condensed with the formation of mutually induced van der Waals dipole interactions. As a measure of the nascent bond between two noble gas atoms used to calculate the limiting separation for condensation, consider that the experimental bond energies of diatomic molecules of helium and argon, for example, are only 49.7 meV and 49 meV, respectively [21]. This is a factor of about 100 smaller than the bond energy of a carbon-carbon bond that is the form of nascent bond in graphite. Thus, the corresponding energy of the interspecies interaction is smaller and the van der Waals spacing is larger, except wherein the nascent bond energy as a function of separation distance mitigates this relationship to some extent. The nature of the helium bonding is solved using the same approach as that of other functional groups given in the Organic Molecular Functional Groups and Molecules section.

Helium is a two-electron neutral atom with both electrons paired as mirror-image current densities in a shell of radius $0.566987a_0$ (Eq. (7.35)). Thus, in isolation or at sufficient separation, there is no energy between helium atoms. The absence of any force such as so-called long-range London forces having a $r^{-n};n>2$ dependency is confirmed by elastic electron scattering from helium atoms as shown in the Electron Scattering Equation for the Helium Atom Based on the Atomic Orbital Model section. However, reversible mutual van der Waals dipoles may be induced by collisions when the atoms are in close proximity such that helium gas can condense into a liquid. The physics is similar to the case of graphite except that the dipoles are atomic rather than molecular, and in both cases the limiting separation is based on the formation of a nascent bond to replace the dipole-dipole interaction. Thus, Eq. (16.25) can also be applied to atoms such as helium.

The van der Waals bonding in the helium atom involves hybridizing the one $1s$ AO into $1s^1$ HO orbitals containing two electrons. The total energy of the state is given by the sum over the two electrons. The sum $E_T\left(He,1s^1\right)$ of experimental energies [15] of He and He^+ is:

$$\begin{aligned} E_T\left(He,1s^1\right) &= 54.41776\ eV + 24.587387\ eV \\ &= 79.005147\ eV \end{aligned} \tag{16.94}$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius r_{1s^1} of the $He1s^1$ shell may be calculated from the Coulombic energy using Eq. (15.13):

$$r_{1s^1} = \sum_{n=0}^{1} \frac{(Z-n)e^2}{8\pi\varepsilon_0\left(e79.005147\ eV\right)} = \frac{3e^2}{8\pi\varepsilon_0\left(e79.005147\ eV\right)} = 0.51664a_0 \tag{16.95}$$

where $Z=2$ for helium. Using Eq. (15.14), the Coulombic energy $E_{Coulomb}\left(He,1s^1\right)$ of the outer electron of the van der Waals bound $He1s^1$ shell is:

$$E_{Coulomb}\left(He,1s^1\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{1s^1}} = \frac{-e^2}{8\pi\varepsilon_0 0.51664a_0} = -26.335049\ eV \tag{16.96}$$

To meet the equipotential condition of the union of the two $He1s^1$ HOs in a nascent bond, c_2 of Eqs. (15.2-15.5) and Eq. (15.61) for the nascent $He-He$-bond MO is given by Eq. (15.75) as the ratio of the valance energy of the He AO, $E\left(He\right)=-24.587387\ eV$ and the magnitude of $E_{Coulomb}\left(He,1s^1\right)$ (Eq. (16.96)):

$$c_2\left(He-He, He1s^1HO\right)=\frac{24.587387\ eV}{26.33505\ eV}=0.93364 \tag{16.97}$$

The opposite charge distributions act as symmetrical point charges at the point of maximum separation, each being centered at 1/2 the He-atom radius from the origin. Using the parameters of Eq. (16.97) and $2c'=0.51664a_0=2.73395\ X\ 10^{-11}\ m$ (Eq. (16.95)), the van der Waals dipole of helium is given in Table 16.27.

Table 16.27. The parameters and van der Waals dipole bond moment of the He functional group of liquid helium.

Functional Group	n_1	$(c_1)c_2$	$(C_1)C_2$	$E_B(valence)$	$E_A(valence)$	$\frac{q}{e}$	Bond Length $2c'\ (\AA)$	Bond Moment μ (D)
He	1	0.93364	1	24.587387	26.33505	0.13744	0.273395	0.18049

As in the case with graphite, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{He}=0.18049\ D=6.02040\ X\ 10^{-31}C\cdot m$ (Table 16.27), the van der Waals energy is:

$$E_{van\ der\ Waals}\left(He\right)=2\frac{2\left(\mu_{He}\right)^2}{4\pi\varepsilon_0\left(r_{He...He}\right)^3}=\left(\frac{2\left(6.02040\ X\ 10^{-31}C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{He\text{-}He}a_0}{2C_1C_2}}\right)^3}\right) \tag{16.98}$$

where there are two bonds at each vertex atom.

The helium interatomic distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.98)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter c_2 is the same as that of the helium dipole, and the reduced mass is $\mu=2$. The parameters are summarized in Table 16.28 and Eq. (16.99).

Table 16.28. The energy parameters (eV) of the helium functional group ($He\cdots He$).

Parameters	$He\cdots He$ Group

Substitution of the parameters of Table 16.28 and the interatomic cohesive energy of helium (Eq. (16.98)) into Eq. (16.25) with $R = a_{He\cdots He}$ gives:

$$\frac{-4\left(6.02040\ X\ 10^{-31} C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{He\cdots He}a_0}{2(0.5)(0.93364)^{-1}}}\right)^3} = \left\{\left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{a_{He\cdots He}a_0}{2(0.5)(0.93364)^{-1}}}}\left((0.93364)\left(2-\frac{1}{2}\frac{a_0}{a_{He\cdots He}}\right)\ln\frac{a+\sqrt{\frac{a_{He\cdots He}a_0}{2(0.5)(0.93364)^{-1}}}}{a-\sqrt{\frac{a_{He\cdots He}a_0}{2(0.5)(0.93364)^{-1}}}}-1\right)\right)\right\}$$

$$= \left\{\left(1+2\sqrt{\frac{2\hbar\sqrt{\frac{(0.5)(0.93364)^{-1}\frac{e^2}{4\pi\varepsilon_o\left(a_{He\cdots He}\right)^3}}{m_e}}{m_e c^2}}\right)\right.$$

$$\left.+\left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{(0.93364)e^2}{8\pi\varepsilon_o\left(a_{He\cdots He}\right)^3}-\frac{e^2}{8\pi\varepsilon_o\left(a_{He\cdots He}+\sqrt{\frac{a_{He\cdots He}a_0}{2(0.5)(0.93364)^{-1}}}\right)^3}}{2}}\right\} \tag{16.99}$$

From the energy relationship given by Eq. (16.99) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $He\cdots He$ MO can be solved.

The most convenient way to solve Eq. (16.99) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{He\cdots He} = 13.13271 a_0 = 6.94953\ X\ 10^{-10}\ m \tag{16.100}$$

The component energy parameters at this condition are given in Table 16.28. Substitution of Eq. (16.100) into Eq. (16.22) gives

$$c'_{He\cdots He} = 3.50160 a_0 = 1.85297\ X\ 10^{-10}\ m \tag{16.101}$$

and internuclear distance between neighboring helium atoms:

$$2c'_{He\cdots He} = 7.00320 a_0 = 3.70593\ X\ 10^{-10}\ m = 3.70593\ \text{Å} \tag{16.102}$$

The experimental helium interatomic distance $2c'_{C\cdots C}$ at 4.24K and <2.25 K are [102]:

$$\begin{aligned} 2c'_{He\cdots He}(4.24K) &= 3.72\ X\ 10^{-10}\ m = 3.72\ \text{Å} \\ 2c'_{He\cdots He}(<2.25K) &= 3.70\ X\ 10^{-10}\ m = 3.70\ \text{Å} \end{aligned} \tag{16.103}$$

The other interatomic bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.100) and (16.101) into Eq. (16.23) gives

$$b_{He\cdots He} = c_{He\cdots He} = 12.65729 a_0 = 6.69795\ X\ 10^{-10}\ m \tag{16.104}$$

Substitution of Eqs. (16.100) and (16.101) into Eq. (16.25) gives:

$$e_{He\cdots He} = 0.26663 \tag{16.105}$$

Using Eqs. (16.99) and (16.102) and the relationship that there are two van der Waals bonds per helium atom and two atoms per bond, the van der Waals energy per helium atom is:

$$E_{van\ der\ Waals}(liquid\ He/He) = 0.000799\ eV \tag{16.106}$$

The experimental van der Waals energy calculated from the heat of vaporization per helium atom is [103]:

$$E_{van\ der\ Waals}(liquid\ He) = E_{vapor,4.221K} = 0.0829\ kJ/mole = 0.000859\ eV/He \tag{16.107}$$

At 1.7 K, the viscosity of liquid helium is close to zero, and a characteristic roton scattering dominates over phonon scattering at this temperature and below [104]. The van der Waals bond energy is also equivalent to the roton energy [105, 106]

$$E_{roton}(liquid\ He) = 8.7\ K = 0.00075\ eV \tag{16.108}$$

and the roton is localized within a region of radius $\approx 3.7-4.0$ Å [104, 106-108] that matches the $He\cdots He$ van der Waals bond distance (Eq. (16.102)). The origin of the roton energy and its cross section as belonging to the van der Waals bond resolves its nature. Independent of this result, the modern view of the roton is that it is not considered associated with the excitation of

vorticity as it was historically; rather it is considered to be due to short-wavelength phonon excitations [105]. Its role in scattering free electrons in superfluid helium is discussed in the Free Electrons in Superfluid Helium are Real in the Absence of Measurement Requiring a Connection of ψ to Physical Reality section. The calculated results based on first principles and given by analytical equations are summarized in Table 16.29.

Table 16.29. The calculated and experimental geometrical parameters and interatomic van der Waals cohesive energy of liquid helium.

Parameter	Calculated	Experimental	Ref. for Exp.
Liquid Helium Interatomic Distance $2c'_{C\text{-}C}$	3.70593 Å	3.72 Å (T=4.24 K) 3.70 (T<2.25K)	102
Roton Length Scale	3.70593 Å	3.7-4.0 Å	104, 106-108
van der Waals Energy per Helium Atom (4.221 K)	0.000799 eV	0.000859 eV	103
Roton Energy	0.000799 eV	0.00075 eV	105, 106

Helium exhibits unique behavior due to its possible phases based on the interplay of the factors that determine the van der Waals bonding at a given temperature and pressure to achieve an energy minimum. In extreme cases of sufficient ultra-low temperatures with the atoms driven in phase with an external excitation field such that the formation of a van der Waals-dipole-bound macromolecular state or other forms of bonding, such as metallic bonding in the case of alkali metals or van der Waals bonding in meta-stable helium atoms, are suppressed, a pure statistical thermodynamic state called a Bose-Einstein condensate [109] (BEC)[1] can form having a predominant population of the atoms in a single, lowest-energy translational state in the trap. Since helium has only two electrons in an outer s-shell having a small diameter, the dipole moment is too weak to form transverse dipoles associated with packing. Specifically, with the angular dependence of packed dipoles interactions, the van der Waals energy $E_{van\ der\ Waals}(He)$ (Eqs. (16.98) and (16.99)) between neighboring dipoles becomes less than the vibrational energy in the transition state ($\bar{E}_{Kvib}$ term of Eq. (16.99) from Eq. (15.53)). Consequently, helium can only mutually induce and form linear dipole-dipole bonds having end-to-end interactions as an energy minimum. Interposed atoms can form a non-bonded phase having correlated translational motion and obeying Bose-Einstein statistics. This phase forms a Bose-Einstein condensate (BEC) as an energy minimum wherein the translations are synchronous. Since a phase comprised of linearly ordered unit cells held together by dipole interactions, specifically van der Waals dipole interactions, can exist with a BEC phase, super-fluidity can arise wherein the lines of bound dipoles move without friction relative to the BEC phase having correlated-translational motion. The linear bonding is also the origin of quantized vortex rings that enter as quantized vortex lines to form rings.

The van der Waals bonds undergo breakage and formation and exist on a time-average basis depending on the internal energy and pressure as in the case of liquid water. The van der Waals bonding exhibits a maximum extent as the temperature is lowered below the boiling point, and the BEC phase comprises the balance of the atoms as the temperature is further lowered to absolute zero. Helium cannot form a solid without application of high pressure to decrease the interatomic separation and permit energetically favorable transverse dipole interactions as well as linear ones. In contrast, other noble gases such as Ne, Ar, Kr, and Xe each possess additional shells including an outer p-shell having a relatively larger radius that gives rise to a significant bond moment supportive of dipole packing interactions; thus, these gases can form solids without the application of high pressure.

GEOMETRICAL PARAMETERS AND ENERGIES DUE TO THE INTERATOMIC VAN DER WAALS COHESIVE ENERGY OF SOLID NEON

Neon is a ten-electron neutral atom having the electron configuration $1s^2 2s^2 2p^6$ with the electrons of each shell paired as mirror-image current densities in a shell wherein the radius of the outer shell is $r_{10} = 0.63659 a_0$ (Eq. (10.202)). Thus, in isolation or at sufficient separation, there is no energy between neon atoms. However, reversible mutual van der Waals dipoles may be induced by collisions when the atoms are in close proximity such that neon gas can condense into a liquid and further solidify at sufficiently low temperatures due to the strong dipole moment that accommodates close packing. As in the case of helium, the dipoles are atomic rather than molecular, and the limiting separation is based on the formation of a nascent bond to replace the dipole-dipole interaction. Thus, Eq. (16.25) can also be applied to neon atoms.

[1] The BEC is incorrectly interpreted as a single large atom having a corresponding probability wave function of quantum mechanics. Since excitation occurs in units of $\hbar$ in order of to conserve angular momentum as shown previously for electronic (Chapter 2), vibrational (Chapter 11), rotational (Chapter 12), and translational excitation (Chapter 3) and Bose-Einstein statistics arise from an underlying deterministic physics (Chapter 24), this state comprised of an ensemble of individual atoms is predicted classically using known equations [110]. As in the case of the coherent state of photons in a laser cavity (Chapter 4), the coherency of the BEC actually disproves the inherent Heisenberg Uncertainty Principle (HUP) of quantum mechanics since the atomic positions and energies are precisely determined simultaneously. Furthermore, it is possible to form a BEC comprising molecules in addition to atoms [111] wherein the molecules lack zero-order vibration in contradiction to the HUP. The classical physics underlying Bose-Einstein statistics was covered in the Statistical Mechanics section.

The van der Waals bonding in the neon atom involves hybridizing the three $2p$ AOs into $2p^3$ HO orbitals containing six electrons. The total energy of the state is given by the sum over the six electrons. The sum $E_T\left(Ne,2p^3\right)$ of experimental energies [15] of Ne, Ne^+, Ne^{2+}, Ne^{3+}, Ne^{4+}, and Ne^{5+} is

$$E_T\left(Ne,2p^3\right)=\begin{pmatrix}157.93\ eV+126.21\ eV+97.12\ eV\\ +63.45\ eV+40.96296\ eV+21.56454\ eV\end{pmatrix}=507.2375\ eV \tag{16.109}$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius r_{2p^3} of the $Ne2p^3$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$r_{2p^3}=\sum_{n=4}^{9}\frac{(Z-n)e^2}{8\pi\varepsilon_0\left(e507.2375\ eV\right)}=\frac{21e^2}{8\pi\varepsilon_0\left(e507.2375\ eV\right)}=0.56329a_0 \tag{16.110}$$

where $Z=10$ for neon. Using Eq. (15.14), the Coulombic energy $E_{Coulomb}\left(Ne,2p^3\right)$ of the outer electron of the van der Waals bound $Ne2p^3$ shell is:

$$E_{Coulomb}\left(Ne,2p^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{2p^3}}=\frac{-e^2}{8\pi\varepsilon_0 0.56329a_0}=-24.154167\ eV \tag{16.111}$$

To meet the equipotential condition of the union of the two $Ne2p^3$ HOs in a nascent bond, c_2 of Eqs. (15.2-15.5) and Eq. (15.61) for the nascent $Ne-Ne$-bond MO is given by Eq. (15.75) as the ratio of the valance energy of the Ne AO, $E\left(Ne\right)=-21.56454\ eV$ and the magnitude of $E_{Coulomb}\left(Ne,2p^3\right)$ (Eq. (16.111)).

$$c_2\left(Ne-Ne,Ne2p^3HO\right)=\frac{21.56454\ eV}{24.154167\ eV}=0.89279 \tag{16.112}$$

The opposite charge distributions act as symmetrical point charges at the point of maximum separation, each being centered at 1/2 the Ne-atom radius from the origin. Using the parameters of Eq. (16.112) and $2c'=0.56329a_0=2.98080\ X\ 10^{-11}\ m$ (Eq. (16.110)), the van der Waals dipole of neon is given in Table 16.30.

Table 16.30. The parameters and van der Waals dipole bond moment of the Ne functional group of solid neon.

Functional Group	n_1	$(c_1)c_2$	$(C_1)C_2$	$E_B\left(valence\right)$	$E_A\left(valence\right)$	$\frac{q}{e}$	Bond Length $2c'\ \left(\AA\right)$	Bond Moment μ (D)
Ne	1	0.89279	1	21.56454	24.15417	0.22730	0.298080	0.32544

The minimum-energy packing of neon dipoles is face-centered cubic also called cubic close packing. In this case, each neon atom has 12 nearest neighbors and the angle between the aligned dipoles is $\frac{\pi}{4}$ radians. As in the case with graphite, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{Ne}=0.32544\ D=1.08554\ X\ 10^{-30}C\cdot m$ (Table 16.30), the van der Waals energy is**:**

$$E_{van\ der\ Waals}\left(Ne\right)=12\frac{2\left(\mu_{Ne}\right)^2}{4\pi\varepsilon_0\left(r_{Ne\cdots Ne}\right)^3}\cos\left(\frac{\pi}{4}\right)=\left(\frac{24\left(1.08554\ X\ 10^{-30}C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{Ne\cdots Ne}a_0}{2C_1C_2}}\right)^3}\right)\cos\left(\frac{\pi}{4}\right) \tag{16.113}$$

The neon interatomic distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.113)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter c_2 is the same as that of the neon dipole, and the reduced mass is $\mu=10$. The parameters are summarized in Table 16.31 and Eq. (16.114).

Table 16.31. The energy parameters (eV) of the neon functional group ($Ne\cdots Ne$).

Substitution of the parameters of Table 16.31 and the interatomic cohesive energy of neon (Eq. (16.113)) into Eq. (16.25) with $R = a_{Ne\cdots Ne}$ gives:

$$\frac{-24\left(1.08554\ X\ 10^{-30} C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{Ne\cdots Ne}a_0}{2(0.5)(0.89279)^{-1}}}\right)^3}\cos\left(\frac{\pi}{4}\right)$$

$$= \left\{\left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{a_{Ne\cdots Ne}a_0}{2(0.5)(0.89279)^{-1}}}}\left((0.89279)\left(2-\frac{1}{2}\frac{a_0}{a_{Ne\cdots Ne}}\right)\ln\frac{a+\sqrt{\frac{a_{Ne\cdots Ne}a_0}{2(0.5)(0.89279)^{-1}}}}{a-\sqrt{\frac{a_{Ne\cdots Ne}a_0}{2(0.5)(0.89279)^{-1}}}}-1\right)\right)\right.$$

$$\left.+\left(1+2\sqrt{\frac{2\hbar\sqrt{\frac{(0.5)(0.89279)^{-1}\frac{e^2}{4\pi\varepsilon_o\left(a_{Ne\cdots Ne}\right)^3}}{m_e}}{m_e c^2}}\right)+\left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{(0.89279)e^2}{8\pi\varepsilon_o\left(a_{Ne\cdots Ne}\right)^3}-\frac{e^2}{8\pi\varepsilon_o\left(a_{Ne\cdots Ne}+\sqrt{\frac{a_{Ne\cdots Ne}a_0}{2(0.5)(0.89279)^{-1}}}\right)^3}}{10}}\right\} \tag{16.114}$$

From the energy relationship given by Eq. (16.114) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $Ne\cdots Ne$ MO can be solved.

The most convenient way to solve Eq. (16.114) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{Ne\cdots Ne} = 11.33530 a_0 = 5.99838\ X\ 10^{-10}\ m \tag{16.115}$$

The component energy parameters at this condition are given in Table 16.31. Substitution of Eq. (16.115) into Eq. (16.22) gives

$$c'_{Ne\cdots Ne} = 3.18120 a_0 = 1.68342\ X\ 10^{-10}\ m \tag{16.116}$$

and internuclear distance between neighboring neon atoms:

$$2c'_{Ne\cdots Ne} = 6.36239 a_0 = 3.36683\ X\ 10^{-10}\ m = 3.36683\ \text{Å} \tag{16.117}$$

The experimental neon interatomic distance $2c'_{C\cdots C}$ at the melting point of 24.48 K is [112, 113]:

$$2c'_{Ne\cdots Ne}(24.48K) = 3.21\ X\ 10^{-10}\ m = 3.21\ \text{Å} \tag{16.118}$$

The other interatomic bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.115) and (16.116) into Eq. (16.23) gives:

$$b_{Ne\cdots Ne} = c_{Ne\cdots Ne} = 10.87975 a_0 = 5.75732\ X\ 10^{-10}\ m \tag{16.119}$$

Substitution of Eqs. (16.115) and (16.116) into Eq. (16.25) gives:

$$e_{Ne\cdots Ne} = 0.28065 \tag{16.120}$$

A convenient method to calculate the lattice energy is to determine the electric field in solid neon having an electric polarization density corresponding to the aligned dipoles moments, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic form of Gauss' equation. Substitution of the density of solid neon at the melting point $\rho = \frac{1.433\ g}{1\ X\ 10^{-6}\ m^3}$ [113], the $MW = 20.179 g/mole$, $N_A = 6.0221415\ X\ 10^{23}\ molecules/mole$, and the neon dipole moment given in Table 16.30 into Eq. (16.53) gives:

$$U(Ne) = \frac{-2(\mu_{Ne})^2\frac{\rho_{solid\ Ne}}{MW}N_A}{3\varepsilon_0} = \frac{-2\left(1.08554\ X\ 10^{-30} C\cdot m\right)^2\frac{\frac{1.433\ g}{1\ X\ 10^{-6}\ m^3}}{20.179 g/mole}6.0221415\ X\ 10^{23}\ molecules/mole}{3\varepsilon_0} \tag{16.121}$$

$$= -0.02368\ eV\ \ (-2.285\ kJ/mole)$$

$U(Ne)$ is also the negative of $E_{van\ der\ Waals}$, the van der Waals energy per neon atom:

$$E_{van\ der\ Waals}\left(solid\ Ne/Ne\right)=0.02368\ eV=2.285\ kJ/mole \tag{16.122}$$

The experimental van der Waals energy calculated from the heat of vaporization and fusion per neon atom at the boiling point and triple point, respectively, is [103] :

$$E_{van\ der\ Waals}\left(solid\ Ne\right)=E_{vapor}+E_{fusion}=0.02125\ eV/Ne=2.0502\ kJ/mole \tag{16.123}$$

The calculated results based on first principles and given by analytical equations are summarized in Table 16.32. Using neon the atomic radius (Eq. (16.110)) and the nearest-neighbor distance (Eq. (16.117)), the lattice structure of neon is shown in Figure 16.17A. The charge density of the van der Waals dipoles of the crystalline lattice is shown in Figure 16.18A.

Table 16.32. The calculated and experimental geometrical parameters and interatomic van der Waals cohesive energy of solid neon.

Parameter	Calculated	Experimental	Ref. for Exp.
Solid Neon Interatomic Distance $2c'_{C-C}$	3.36683 Å	3.21 Å (T=24.48 K)	113
van der Waals Energy per Neon Atom	0.02368 eV	0.02125 eV	103

GEOMETRICAL PARAMETERS AND ENERGIES DUE TO THE INTERATOMIC VAN DER WAALS COHESIVE ENERGY OF SOLID ARGON

Argon is an eighteen-electron neutral atom having the electron configuration $1s^2 2s^2 2p^6 3s^2 3p^6$ with the electrons of each shell paired as mirror-image current densities in a shell wherein the radius of the outer shell is $r_{18}=0.86680a_0$ (Eq. (10.386)). Thus, in isolation or at sufficient separation, there is no energy between argon atoms. However, reversible mutual van der Waals dipoles may be induced by collisions when the atoms are in close proximity such that argon gas can condense into a liquid and further solidify at sufficiently low temperatures due to the strong dipole moment that accommodates close packing. As in the case of helium, the dipoles are atomic rather than molecular, and the limiting separation is based on the formation of a nascent bond to replace the dipole-dipole interaction. Thus, Eq. (16.25) can also be applied to argon atoms.

The van der Waals bonding in the argon atom involves hybridizing the three $3p$ AOs into $3p^3$ HO orbitals containing six electrons. The total energy of the state is given by the sum over the six electrons. The sum $E_T\left(Ar,3p^3\right)$ of experimental energies [15] of Ar, Ar^+, Ar^{2+}, Ar^{3+}, Ar^{4+}, and Ar^{5+} is:

$$E_T\left(Ar,3p^3\right)=\begin{pmatrix}91.009\ eV+75.02\ eV+59.81\ eV\\ +40.74\ eV+27.62966\ eV+15.75961\ eV\end{pmatrix}=309.96827\ eV \tag{16.124}$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius r_{3p^3} of the $Ar3p^3$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$r_{3p^3}=\sum_{n=12}^{17}\frac{(Z-n)e^2}{8\pi\varepsilon_0\left(e309.96827\ eV\right)}=\frac{21e^2}{8\pi\varepsilon_0\left(e309.96827\ eV\right)}=0.92178a_0 \tag{16.125}$$

where $Z=18$ for argon. Using Eq. (15.14), the Coulombic energy $E_{Coulomb}\left(Ar,3p^3\right)$ of the outer electron of the van der Waals bound $Ar3p^3$ shell is

$$E_{Coulomb}\left(Ar,3p^3\right)=\frac{-e^2}{8\pi\varepsilon_0 r_{3p^3}}=\frac{-e^2}{8\pi\varepsilon_0 0.92178a_0}=-14.760394\ eV \tag{16.126}$$

To meet the equipotential condition of the union of the two $Ar3p^3$ HOs in a nascent bond, c_2 of Eqs. (15.2-15.5) and Eq. (15.61) for the nascent $Ar-Ar$-bond MO is given by Eq. (15.75) as the ratio of the valance energy of the Ar AO, $E\left(Ar\right)=-15.75961\ eV$ and the magnitude of $E_{Coulomb}\left(Ar,3p^3\right)$ (Eq. (16.126)).

$$c_2\left(Ar-Ar,Ar3p^3HO\right)=\frac{14.760394\ eV}{15.75961\ eV}=0.93660 \tag{16.127}$$

Since the outer $Ar3p^3$ HO shell is at a lower energy and greater radius than the non-polarized $3p$ shell, the inner shells are polarized as well. The dipole of the outer shell can polarize the inner shells to the limit that the sum of the primary and secondary dipoles is twice the primary scaled by the energy matching factors of the van der Waals bond given in Eq. (16.15). Thus, the limiting dipole due to polarization of the inner shells is given by:

$$\begin{aligned}\mu_{Ar}<2c_1^{-1}qC_2 2c' &= 2\left(0.93660\right)^{-1}\left(0.13110\right)e\left(0.93660\right)^{-1}\left(4.87784\ X\ 10^{-11}\ m\right)\\ &=2.49410\ X\ 10^{-30}C\cdot m=0.74771\ D\end{aligned} \tag{16.128}$$

The condition of Eq. (16.128) is matched by the participation of the outer four shells as given in Table 16.33. At each shell, opposite charge distributions act as symmetrical point charges at the point of maximum separation, each being centered at 1/2 the shell radius from the origin. Using the parameters of Eq. (16.127) and $2c' = 0.92178a_0 = 4.87784\ X\ 10^{-11}\ m$ (Eq. (16.125)) as well as the radii of the inner shells of argon (Table 10.17), the van der Waals dipole of argon is given in Table 16.33 as the sum of the moments of each participating shell.

Table 16.33. The parameters and van der Waals dipole bond moment of the Ar functional group of solid argon.

Functional Group	n_1	(c_1) c_2	(C_1) C_2	$E_B(valence)$	$E_A(valence)$	$\frac{q}{e}$	Bond Length $2c'$ (Å)	Bond Moment μ (D)
Ar	1	0.93660	1	14.76039	15.75961	0.13110	$Ar3p^3$ HO 0.48778 $Ar3s$ AO 0.41422 $Ar2p$ AO 0.15282 $Ar2s$ AO 0.12615	0.74366

The minimum-energy packing of argon dipoles is face-centered cubic also called cubic close packing. In this case, each argon atom has 12 nearest neighbors and the angle between the aligned dipoles is $\frac{\pi}{4}$ radians. As in the case with graphite, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{Ar} = 0.74366\ D = 2.48058\ X\ 10^{-30} C \cdot m$ (Table 16.33), the van der Waals energy is**:**

$$E_{van\ der\ Waals}(Ar) = 12\frac{2(\mu_{Ar})^2}{4\pi\varepsilon_0 (r_{Ar\ldots Ar})^3}\cos\left(\frac{\pi}{4}\right) = \left(\frac{24\left(2.48058\ X\ 10^{-30} C \cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{Ar\ldots Ar}a_0}{2C_1C_2}}\right)^3}\right)\cos\left(\frac{\pi}{4}\right) \tag{16.129}$$

The argon interatomic distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.129)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter c_2 is the same as that of the argon dipole, and the reduced mass is $\mu = 20$. The parameters are summarized in Table 16.34 and Eq. (16.130).

Table 16.34. The energy parameters (eV) of the argon functional group ($Ar\cdots Ar$).

Substitution of the parameters of Table 16.34 and the interatomic cohesive energy of argon (Eq. (16.129)) into Eq. (16.25) with $R=a_{Ar...Ar}$ gives:

$$\frac{-24\left(2.48058\ X\ 10^{-30} C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{Ar\cdots Ar}a_0}{2(0.5)(0.93660)^{-1}}}\right)^3}\cos\left(\frac{\pi}{4}\right)$$

$$= \left\{\left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{a_{Ar\cdots Ar}a_0}{2(0.5)(0.93660)^{-1}}}}\left((0.93660)\left(2-\frac{1}{2}\frac{a_0}{a_{Ar\cdots Ar}}\right)\ln\frac{a+\sqrt{\frac{a_{Ar\cdots Ar}a_0}{2(0.5)(0.93660)^{-1}}}}{a-\sqrt{\frac{a_{Ar\cdots Ar}a_0}{2(0.5)(0.93660)^{-1}}}}-1\right)\right)\right\}$$

$$= \left\{\begin{array}{l}\left(1+2\sqrt{\frac{2\hbar\sqrt{\frac{(0.5)(0.93660)^{-1}\frac{e^2}{4\pi\varepsilon_o\left(a_{Ar\cdots Ar}\right)^3}}{m_e}}{m_e c^2}}\right) \\ +\left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{(0.93660)e^2}{8\pi\varepsilon_o\left(a_{Ar\cdots Ar}\right)^3}-\frac{e^2}{8\pi\varepsilon_o\left(a_{Ar\cdots Ar}+\sqrt{\frac{a_{Ar\cdots Ar}a_0}{2(0.5)(0.93660)^{-1}}}\right)^3}}{20}}\end{array}\right\} \quad (16.130)$$

From the energy relationship given by Eq. (16.130) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $Ar\cdots Ar$ MO can be solved.

The most convenient way to solve Eq. (16.130) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{Ar\cdots Ar} = 12.50271 a_0 = 6.61615\ X\ 10^{-10}\ m \quad (16.131)$$

The component energy parameters at this condition are given in Table 16.34. Substitution of Eq. (16.131) into Eq. (16.22) gives

$$c'_{Ar\cdots Ar} = 3.42199 a_0 = 1.81084\ X\ 10^{-10}\ m \quad (16.132)$$

and internuclear distance between neighboring argon atoms:

$$2c'_{Ar\cdots Ar}(0\ K) = 6.84397 a_0 = 3.62167\ X\ 10^{-10}\ m = 3.62167\ \text{Å} \quad (16.133)$$

The experimental argon interatomic distance $2c'_{C\cdots C}$ is [114]

$$2c'_{Ar\cdots Ar}(4.2\ K) = 3.71\ X\ 10^{-10}\ m = 3.71\ \text{Å} \quad (16.134)$$

The other interatomic bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.131) and (16.132) into Eq. (16.23) gives:

$$b_{Ar\cdots Ar} = c_{Ar\cdots Ar} = 12.02530 a_0 = 6.36351\ X\ 10^{-10}\ m \quad (16.135)$$

Substitution of Eqs. (16.131) and (16.132) into Eq. (16.25) gives:

$$e_{Ar\cdots Ar} = 0.27370 \quad (16.136)$$

A convenient method to calculate the lattice energy is to determine the electric field in solid argon having an electric polarization density corresponding to the aligned dipoles moments, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic form of Gauss' equation. Substitution of the density of solid argon at 4.2 K $\rho = \frac{1.83\ g}{1\ X\ 10^{-6}\ m^3}$ [114], the $MW = 39.948 g/mole$, $N_A = 6.0221415\ X\ 10^{23}\ molecules/mole$, and the argon dipole moment given in Table 16.33 into Eq. (16.53) gives:

$$U(Ar) = \frac{-2(\mu_{Ar})^2\frac{\rho_{solid\ Ar}}{MW}N_A}{3\varepsilon_0}$$

$$= \frac{-2\left(2.48058\ X\ 10^{-30} C\cdot m\right)^2\frac{\frac{1.83\ g}{1\ X\ 10^{-6}\ m^3}}{39.948 g/mole}6.0221415\ X\ 10^{23}\ molecules/mole}{3\varepsilon_0} \quad (16.137)$$

$$= -0.07977\ eV\ \ (-7.697\ kJ/mole)$$

$U(Ar)$ is also the negative of $E_{van\ der\ Waals}$, the van der Waals energy per argon atom:

$$E_{van\ der\ Waals}\left(solid\ Ar, 4.2\ K / Ar\right) = 0.07977\ eV = 7.697\ kJ / mole \tag{16.138}$$

The experimental van der Waals energy is the cohesive energy [115]:

$$E_{van\ der\ Waals}\left(solid\ Ar, 0\ K\right) = 0.08022\ eV / Ar = 7.74\ kJ / mole \tag{16.139}$$

The calculated results based on first principles and given by analytical equations are summarized in Table 16.35. Using argon the atomic radius (Eq. (16.125)) and the nearest-neighbor distance (Eq. (16.133)), the lattice structure of argon is shown in Figure 16.17B. The charge density of the van der Waals dipoles of the crystalline lattice is shown in Figure 16.18B.

Table 16.35. The calculated and experimental geometrical parameters and interatomic van der Waals cohesive energy of solid argon.

Parameter	Calculated	Experimental	Ref. for Exp.
Solid Argon Interatomic Distance $2c'_{C\text{-}C}$	3.62167 Å (T=0 K)	3.71 Å (T=4.2 K)	114
van der Waals Energy per Argon Atom	0.07977 eV (T=4.2 K)	0.08022 eV (T=0 K)	115

GEOMETRICAL PARAMETERS AND ENERGIES DUE TO THE INTERATOMIC VAN DER WAALS COHESIVE ENERGY OF SOLID KRYPTON

Krypton is a thirty-six-electron neutral atom having the electron configuration $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6$ with the electrons of each shell paired as mirror-image current densities in a shell wherein the radius of the outer shell is $r_{36} = 0.97187 a_0$ (Eq. (10.102)). Thus, in isolation or at sufficient separation, there is no energy between krypton atoms. However, reversible mutual van der Waals dipoles may be induced by collisions when the atoms are in close proximity such that krypton gas can condense into a liquid and further solidify at sufficiently low temperatures due to the strong dipole moment that accommodates close packing. As in the case of helium, the dipoles are atomic rather than molecular, and the limiting separation is based on the formation of a nascent bond to replace the dipole-dipole interaction. Thus, Eq. (16.25) can also be applied to krypton atoms.

The van der Waals bonding in the krypton atom involves hybridizing the three $4p$ AOs into $4p^3$ HO orbitals containing six electrons. The total energy of the state is given by the sum over the six electrons. The sum $E_T\left(Kr, 4p^3\right)$ of experimental energies [15, 116-119] of Kr, Kr^+, Kr^{2+}, Kr^{3+}, Kr^{4+}, and Kr^{5+} is:

$$E_T\left(Kr, 4p^3\right) = \begin{pmatrix} 78.5\ eV + 64.7\ eV + 52.5\ eV \\ +36.950\ eV + 24.35984\ eV + 13.99961\ eV \end{pmatrix} = 271.00945\ eV \tag{16.140}$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius r_{4p^3} of the $Kr4p^3$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$r_{4p^3} = \sum_{n=30}^{35} \frac{(Z-n)e^2}{8\pi\varepsilon_0\left(e271.00945\ eV\right)} = \frac{21e^2}{8\pi\varepsilon_0\left(e271.00945\ eV\right)} = 1.05429 a_0 \tag{16.141}$$

where $Z = 36$ for krypton. Using Eq. (15.14), the Coulombic energy $E_{Coulomb}\left(Kr, 4p^3\right)$ of the outer electron of the van der Waals bound $Kr4p^3$ shell is:

$$E_{Coulomb}\left(Kr, 4p^3\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{4p^3}} = \frac{-e^2}{8\pi\varepsilon_0 1.05429 a_0} = -12.905212\ eV \tag{16.142}$$

To meet the equipotential condition of the union of the two $Kr4p^3$ HOs in a nascent bond, c_2 of Eqs. (15.2-15.5) and Eq. (15.61) for the nascent $Kr-Kr$-bond MO is given by Eq. (15.75) as the ratio of the valance energy of the Kr AO, $E\left(Kr\right) = -13.99961\ eV$ and the magnitude of $E_{Coulomb}\left(Kr, 4p^3\right)$ (Eq. (16.142)).

$$c_2\left(Kr - Kr, Kr4p^3 HO\right) = \frac{12.905212\ eV}{13.99961\ eV} = 0.92183 \tag{16.143}$$

Since the outer $Kr4p^3$ HO shell is at a lower energy and greater radius than the non-polarized $4p$ shell, the inner shells are polarized as well. The dipole of the outer shell can polarize the inner shells to the limit that the sum of the primary and secondary dipoles is twice the primary scaled by the energy matching factors of the van der Waals bond given in Eq. (16.15). Thus, the limiting dipole due to polarization of the inner shells is given by:

$$\begin{aligned} \mu_{Kr} &< 2c_1^{-1} q C_2 2c' = 2\left(0.16298\right) e \left(0.92183\right)^{-1} \left(5.57905\ X\ 10^{-11}\ m\right) \\ &= 3.42870\ X\ 10^{-30} C \cdot m = 1.02790\ D \end{aligned} \tag{16.144}$$

The condition of Eq. (16.144) is matched by the participation of the outer three shells as given in Table 16.36. At each shell, opposite charge distributions act as symmetrical point charges at the point of maximum separation, each being centered at 1/2 the

shell radius from the origin. Using the parameters of Eq. (16.143) and $2c' = 1.05429a_0 = 5.57905\,X\,10^{-11}\,m$ (Eq. (16.141)) as well as the radii of the inner shells of krypton (Eq. (10.102)), the van der Waals dipole of krypton is given in Table 16.36 as the sum of the moments of each participating shell.

Table 16.36. The parameters and van der Waals dipole bond moment of the Kr functional group (FG) of solid krypton.

FG	n_1	(c_1) c_2	(C_1) C_2	$E_B(valence)$	$E_A(valence)$	$\frac{q}{e}$	*Ion / IP / Z* [116-119]	Bond Length $2c'$ (Å) (Eqs. (16.141) and (10.102))	Bond Moment μ (D)
Kr	1	0.92183	1	12.90521	13.99961	0.16298	Kr^{6+} 111.0 7 Kr^{8+} 231.5 9	$Kr4p^3$ HO 0.55790 $Kr4s$ AO 0.45405 $Kr3d$ AO 0.27991	1.01129

The minimum-energy packing of krypton dipoles is face-centered cubic also called cubic close packing. In this case, each krypton atom has 12 nearest neighbors and the angle between the aligned dipoles is $\frac{\pi}{4}$ radians. As in the case with graphite, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{Kr} = 1.01129\,D = 3.37329\,X\,10^{-30} C \cdot m$ (Table 16.36), the van der Waals energy is**:**

$$E_{van\ der\ Waals}(Kr) = 12\frac{2(\mu_{Kr})^2}{4\pi\varepsilon_0 (r_{Kr\ldots Kr})^3}\cos\left(\frac{\pi}{4}\right) = \left(\frac{24\left(3.37329\,X\,10^{-30} C \cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{Kr\ldots Kr}a_0}{2C_1C_2}}\right)^3}\right)\cos\left(\frac{\pi}{4}\right) \tag{16.145}$$

The krypton interatomic distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.145)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter c_2 is the same as that of the krypton dipole, and the reduced mass is $\mu = 42$. The parameters are summarized in Table 16.37 and Eq. (16.146).

Table 16.37. The energy parameters (eV) of the krypton functional group ($Kr\cdots Kr$).

Substitution of the parameters of Table 16.37 and the interatomic cohesive energy of krypton (Eq. (16.145)) into Eq. (16.25) with $R=a_{Kr\ldots Kr}$ gives:

$$\frac{-24\left(3.37329\ X\ 10^{-31} C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{Kr\cdots Kr}a_0}{2(0.5)(0.92183)}}\right)^3}\cos\left(\frac{\pi}{4}\right)$$

$$= \left\{\left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{a_{Kr\cdots Kr}a_0}{2(0.5)(0.92183)}}}\left((0.92183)\left(2-\frac{1}{2}\frac{a_0}{a_{Kr\cdots Kr}}\right)\ln\frac{a+\sqrt{\frac{a_{Kr\cdots Kr}a_0}{2(0.5)(0.92183)}}}{a-\sqrt{\frac{a_{Kr\cdots Kr}a_0}{2(0.5)(0.92183)}}}-1\right)\right)\right.$$

$$\left.+\left(1+2\sqrt{\frac{2\hbar\sqrt{\frac{(0.5)(0.92183)\frac{e^2}{4\pi\varepsilon_o\left(a_{Kr\cdots Kr}\right)^3}}{m_e}}{m_e c^2}}\right)\right.$$

$$\left.+\left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{(0.92183)e^2}{8\pi\varepsilon_o\left(a_{Kr\cdots Kr}\right)^3}-\frac{e^2}{8\pi\varepsilon_o\left(a_{Kr\cdots Kr}+\sqrt{\frac{a_{Kr\cdots Kr}a_0}{2(0.5)(0.92183)}}\right)^3}}{42}}\right\} \tag{16.146}$$

From the energy relationship given by Eq. (16.146) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $Kr\cdots Kr$ MO can be solved.

The most convenient way to solve Eq. (16.146) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{Kr\cdots Kr} = 13.74580 a_0 = 7.27396\ X\ 10^{-10}\ m \tag{16.147}$$

The component energy parameters at this condition are given in Table 16.37. Substitution of Eq. (16.147) into Eq. (16.22) gives

$$c'_{Kr\cdots Kr} = 3.86154 a_0 = 2.04344\ X\ 10^{-10}\ m \tag{16.148}$$

and internuclear distance between neighboring krypton atoms:

$$2c'_{Kr\cdots Kr}\left(0\ K\right) = 7.72308 a_0 = 4.08688\ X\ 10^{-10}\ m = 4.08688\ \mathring{A} \tag{16.149}$$

The experimental krypton interatomic distance $2c'_{C\cdots C}$ is [113]

$$2c'_{Kr\cdots Kr}\left(0\ K\right) = 3.992\ \ X\ 10^{-10}\ m = 3.992\ \ \mathring{A} \tag{16.150}$$

The other interatomic bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.147) and (16.148) into Eq. (16.23) gives:

$$b_{Kr\cdots Kr} = c_{Kr\cdots Kr} = 13.19225 a_0 = 6.98104\ X\ 10^{-10}\ m \tag{16.151}$$

Substitution of Eqs. (16.147) and (16.148) into Eq. (16.25) gives:

$$e_{Kr\cdots Kr} = 0.28092 \tag{16.152}$$

A convenient method to calculate the lattice energy is to determine the electric field in solid krypton having an electric polarization density corresponding to the aligned dipoles moments, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic form of Gauss' equation. Substitution of the density of solid krypton at 4.2 K $\rho = \frac{3.094\ g}{1\ X\ 10^{-6}\ m^3}$ [113], the $MW = 83.80 g/mole$, $N_A = 6.0221415\ X\ 10^{23}\ molecules/mole$, and the krypton dipole moment given in Table 16.36 into Eq. (16.53) gives:

$$U\left(Kr\right) = \frac{-2\left(\mu_{Kr}\right)^2\frac{\rho_{solid\ Kr}}{MW}N_A}{3\varepsilon_0}$$

$$= \frac{-2\left(3.37329\ X\ 10^{-30} C\cdot m\right)^2\frac{\frac{3.094\ g}{1\ X\ 10^{-6}\ m^3}}{83.80 g/mole}6.0221415\ X\ 10^{23}\ molecules/mole}{3\varepsilon_0} \tag{16.153}$$

$$= -0.11890\ eV\ \ \left(-11.472\ kJ/mole\right)$$

$[U\left(Kr\right)]$ is also the negative of $E_{van\ der\ Waals}$, the van der Waals energy per krypton atom:

$$E_{van\ der\ Waals}\left(solid\ Kr, 0\ K / Kr\right) = 0.11890\ eV = 11.472\ kJ / mole \tag{16.154}$$

The experimental van der Waals energy is the cohesive energy [120]:

$$E_{van\ der\ Waals}\left(solid\ Kr, 0\ K / Kr\right) = 0.11561\ eV = 11.15454\ kJ / mole \tag{16.155}$$

The calculated results based on first principles and given by analytical equations (0 K) are summarized in Table 16.38. Using krypton the atomic radius (Eq. (16.141)) and the nearest-neighbor distance (Eq. (16.149)), the lattice structure of krypton is shown in Figure 16.15C. The charge density of the van der Waals dipoles of the crystalline lattice is shown in Figure 16.16C.

Table 16.38. The calculated and experimental geometrical parameters and interatomic van der Waals cohesive energy (0 K) of solid krypton.

Parameter	Calculated	Experimental	Ref. for Exp.
Solid Krypton Interatomic Distance $2c'_{C-C}$	4.08688 Å	3.992 Å	113
van der Waals Energy per Krypton Atom	0.11890 eV	0.11561 eV	120

GEOMETRICAL PARAMETERS AND ENERGIES DUE TO THE INTERATOMIC VAN DER WAALS COHESIVE ENERGY OF SOLID XENON

Xenon is a fifty-four-electron neutral atom having the electron configuration $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^{10} 5s^2 5p^6$ with the electrons of each shell paired as mirror-image current densities in a shell wherein the radius of the outer shell is $r_{54} = 1.12168 a_0$ (Eq. (10.102)). Thus, in isolation or at sufficient separation, there is no energy between xenon atoms. However, reversible mutual van der Waals dipoles may be induced by collisions when the atoms are in close proximity such that xenon gas can condense into a liquid and further solidify at sufficiently low temperatures due to the strong dipole moment that accommodates close packing. As in the case of helium, the dipoles are atomic rather than molecular, and the limiting separation is based on the formation of a nascent bond to replace the dipole-dipole interaction. Thus, Eq. (16.25) can also be applied to xenon atoms.

The van der Waals bonding in the xenon atom involves hybridizing the three $5p$ AOs into $5p^3$ HO orbitals containing six electrons. The total energy of the state is given by the sum over the six electrons. The sum $E_T\left(Xe, 5p^3\right)$ of experimental energies [15, 121-122] of Xe, Xe^+, Xe^{2+}, Xe^{3+}, Xe^{4+}, and Xe^{5+} is:

$$E_T\left(Xe, 5p^3\right) = \begin{pmatrix} 66.703\ eV + 54.14\ eV + 40.9\ eV \\ +31.050\ eV + 20.975\ eV + 12.129842\ eV \end{pmatrix} = 225.89784\ eV \tag{16.156}$$

By considering that the central field decreases by an integer for each successive electron of the shell, the radius r_{5p^3} of the $Xe5p^3$ shell may be calculated from the Coulombic energy using Eq. (15.13).

$$r_{5p^3} = \sum_{n=48}^{53} \frac{(Z-n)e^2}{8\pi\varepsilon_0\left(e225.897842\ eV\right)} = \frac{21e^2}{8\pi\varepsilon_0\left(e225.897842\ eV\right)} = 1.26483 a_0 \tag{16.157}$$

where $Z = 54$ for xenon. Using Eq. (15.14), the Coulombic energy $E_{Coulomb}\left(Xe, 5p^3\right)$ of the outer electron of the van der Waals bound $Xe5p^3$ shell is:

$$E_{Coulomb}\left(Xe, 5p^3\right) = \frac{-e^2}{8\pi\varepsilon_0 r_{5p^3}} = \frac{-e^2}{8\pi\varepsilon_0 1.26483 a_0} = -10.757040\ eV \tag{16.158}$$

To meet the equipotential condition of the union of the two $Xe5p^3$ HOs in a nascent bond, c_2 of Eqs. (15.2-15.5) and Eq. (15.61) for the nascent $Xe-Xe$-bond MO is given by Eq. (15.75) as the ratio of the valance energy of the Xe AO, $E\left(Xe\right) = -12.129842\ eV$ and the magnitude of $E_{Coulomb}\left(Xe, 5p^3\right)$ (Eq. (16.158)).

$$c_2\left(Xe - Xe, Xe5p^3 HO\right) = \frac{10.75704\ eV}{12.129842\ eV} = 0.88682 \tag{16.159}$$

Since the outer $Xe5p^3$ HO shell is at a lower energy and greater radius than the non-polarized $5p$ shell, the inner shells are polarized as well. The dipole of the outer shell can polarize the inner shells to the limit that the sum of the primary and secondary dipoles is twice the primary scaled by the energy matching factors of the van der Waals bond given in Eq. (16.15). Thus, the limiting dipole due to polarization of the inner shells is given by:

$$\mu_{Xe} < 2c_1^{-1} q C_2 2c' = 2\left(0.24079\right)e\left(0.88682\right)\left(6.69318\ X\ 10^{-11}\ m\right) = 5.16444\ X\ 10^{-30} C \cdot m = 1.54826\ D \tag{16.160}$$

The condition of Eq. (16.160) is matched by the participation of the outer two shells as given in Table 16.39. At each shell, opposite charge distributions act as symmetrical point charges at the point of maximum separation, each being centered at 1/2 the shell radius from the origin. Using the parameters of Eq. (16.159) and $2c' = 1.26483 a_0 = 6.69318\ X\ 10^{-11}\ m$ (Eq. (16.157)) as

well as the radius of the inner $5s$ shell of xenon (Eq. (10.102)), the van der Waals dipole of xenon is given in Table 16.39 as the sum of the moments of each participating shell.

Table 16.39. The parameters and van der Waals dipole bond moment of the *Xe* functional group (FG) of solid xenon.

FG	n_1	(c_1) c_2	(C_1) C_2	$E_B(valence)$	$E_A(valence)$	$\frac{q}{e}$	*Ion* / *IP* / *Z* [121-122]	Bond Length $2c'$ $(\mathring{A})$ (Eqs. (16.157) and (10.102))	Bond Moment μ (D)
Xe	1	0.88682	1	10.75704	12.12984	0.24079	Xe^{6+} 91.6 7	$Xe5p^3$ HO 0.66932 $Xe5s$ AO 0.55021	1.41050

The minimum-energy packing of xenon dipoles is face-centered cubic also called cubic close packing. In this case, each xenon atom has 12 nearest neighbors and the angle between the aligned dipoles is $\frac{\pi}{4}$ radians. As in the case with graphite, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{Xe} = 1.41050\ D = 4.70492\ X\ 10^{-30} C \cdot m$ (Table 16.39), the van der Waals energy is**:**

$$E_{van\ der\ Waals}(Xe) = 12\frac{2(\mu_{Xe})^2}{4\pi\varepsilon_0 (r_{Xe\ldots Xe})^3}\cos\left(\frac{\pi}{4}\right) = \left(\frac{24\left(4.70492\ X\ 10^{-30} C \cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{Xe\ldots Xe}a_0}{2C_1C_2}}\right)^3}\right)\cos\left(\frac{\pi}{4}\right) \tag{16.161}$$

The xenon interatomic distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.161)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter c_2 is the same that of the xenon dipole, and the reduced mass is $\mu = 65$. The parameters are summarized in Table 16.40 and Eq. (16.162).

Table 16.40. The energy parameters (eV) of the xenon functional group ($Xe\cdots Xe$).

Substitution of the parameters of Table 16.40 and the interatomic cohesive energy of xenon (Eq. (16.161)) into Eq. (16.25) with $R=a_{Xe...Xe}$ gives:

$$\frac{-24\left(4.70492\ X\ 10^{-31} C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{Xe\cdots Xe}a_0}{2(0.5)(0.88682)}}\right)^3}\cos\left(\frac{\pi}{4}\right)$$

$$= \left\{\left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{a_{Xe\cdots Xe}a_0}{2(0.5)(0.88682)}}}\left(\left(2-\frac{1}{2}\frac{a_0}{a_{Xe\cdots Xe}}\right)\ln\frac{a+\sqrt{\frac{a_{Xe\cdots Xe}a_0}{2(0.5)(0.88682)}}}{a-\sqrt{\frac{a_{Xe\cdots Xe}a_0}{2(0.5)(0.88682)}}}-1\right)\right)\right.$$

$$\left.\left(1+2\sqrt{\frac{2\hbar\sqrt{\frac{(0.5)(0.88682)\frac{e^2}{4\pi\varepsilon_o\left(a_{Xe\cdots Xe}\right)^3}}{m_e}}{m_e c^2}}\right)\right\} \tag{16.162}$$

$$\left.+\left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{e^2}{8\pi\varepsilon_o\left(a_{Xe\cdots Xe}\right)^3}-\frac{e^2}{8\pi\varepsilon_o\left(a_{Xe\cdots Xe}+\sqrt{\frac{a_{Xe\cdots Xe}a_0}{2(0.5)(0.88682)}}\right)^3}}{65}}\right\}$$

From the energy relationship given by Eq. (16.162) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $Xe\cdots Xe$ MO can be solved.

The most convenient way to solve Eq. (16.162) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{Xe\cdots Xe} = 15.94999 a_0 = 8.44037\ X\ 10^{-10}\ m \tag{16.163}$$

The component energy parameters at this condition are given in Table 16.40. Substitution of Eq. (16.163) into Eq. (16.22) gives

$$c'_{Xe\cdots Xe} = 4.24093 a_0 = 2.24420\ X\ 10^{-10}\ m \tag{16.164}$$

and internuclear distance between neighboring xenon atoms:

$$2c'_{Xe\cdots Xe}\left(0\ K\right) = 8.48187 a_0 = 4.48841\ X\ 10^{-10}\ m = 4.48841\ \mathring{A} \tag{16.165}$$

The experimental xenon interatomic distance $2c'_{C\cdots C}$ at the melting point of 161.35 K is [112, 113]:

$$2c'_{Xe\cdots Xe}\left(161.35\ K\right) = 4.492\ \ X\ 10^{-10}\ m = 4.492\ \ \mathring{A} \tag{16.166}$$

The other interatomic bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.163) and (16.164) into Eq. (16.23) gives:

$$b_{Xe\cdots Xe} = c_{Xe\cdots Xe} = 15.37585 a_0 = 8.13655\ X\ 10^{-10}\ m \tag{16.167}$$

Substitution of Eqs. (16.163) and (16.164) into Eq. (16.25) gives:

$$e_{Xe\cdots Xe} = 0.26589 \tag{16.168}$$

A convenient method to calculate the lattice energy is to determine the electric field in solid xenon having an electric polarization density corresponding to the aligned dipoles moments, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic form of Gauss' equation. Substitution of the density of solid xenon at 0 K $\rho = \frac{3.780\ g}{1\ X\ 10^{-6}\ m^3}$ [113], the $MW = 131.29 g/mole$, $N_A = 6.0221415\ X\ 10^{23}\ molecules/mole$, and the xenon dipole moment given in Table 16.39 into Eq. (16.53) gives:

$$U\left(Xe\right) = \frac{-2\left(\mu_{Xe}\right)^2\frac{\rho_{solid\ Xe}}{MW}N_A}{3\varepsilon_0}$$

$$= \frac{-2\left(4.70492\ X\ 10^{-30} C\cdot m\right)^2\frac{\frac{3.780\ g}{1\ X\ 10^{-6}\ m^3}}{131.29 g/mole}6.0221415\ X\ 10^{23}\ molecules/mole}{3\varepsilon_0} \tag{16.169}$$

$$= -0.18037\ eV\ \ \left(-17.403\ kJ/mole\right)$$

$U(Xe)$ is also the negative of $E_{van\ der\ Waals}$, the van der Waals energy per xenon atom:

$$E_{van\ der\ Waals}(solid\ Xe, 0\ K / Xe) = 0.18037\ eV = 17.403\ kJ / mole \tag{16.170}$$

The experimental van der Waals energy is the cohesive energy [123]:

$$E_{van\ der\ Waals}(solid\ Xe, 0\ K) = 0.16608\ eV / Xe = 16.02472\ kJ / mole \tag{16.171}$$

The calculated results based on first principles and given by analytical equations are summarized in Table 16.41. Using xenon the atomic radius (Eq. (16.157)) and the nearest-neighbor distance (Eq. (16.165)), the lattice structure of xenon is shown in Figure 16.15D. The charge density of the van der Waals dipoles of the crystalline lattice is shown in Figure 16.16D.

Table 16.41. The calculated and experimental geometrical parameters and interatomic van der Waals cohesive energy of solid xenon.

GEOMETRICAL PARAMETERS AND ENERGIES DUE TO THE INTERMOLECULAR VAN DER WAALS COHESIVE ENERGIES OF H_2 DIMER, SOLID H_2, $H_2(1/p)$ DIMER, AND SOLID $H_2(1/p)$

Molecular hydrogen and molecular hydrino are typically gaseous molecules having no net electric field. But, at very low temperatures it is possible to form diffuse dimers, or alternatively, these gases may be condensed with the formation of mutually induced van der Waals dipole interactions. The nature of the van der Waals bonding of molecular hydrogen and molecular hydrino is solved using the same approach as that of condensed helium atoms, except analogously with the comparison of isoelectronic helium and H_2 excited states, the prolate spherical coordinate equations replace the spherical coordinate equations of the two-electron system.

Molecular hydrogen and molecular hydrino are each a two-electron neutral molecule with both electrons paired as mirror-image current densities in a prolate spheroidal shell of semimajor and minor axes given by Eqs. (11.202) and (11.205), respectively. Thus, in isolation or at sufficient separation, there is no energy between hydrogen-type molecules. However, reversible mutual van der Waals dipoles may be induced by collisions when the atoms are in close proximity such that hydrogen-type gas can condense into dimers, liquid, and solid states depending on the temperature and pressure. The limiting separation of the corresponding van der Waals bonding between molecular dipoles is based on the formation of a nascent bond to replace the dipole-dipole interaction. Thus, the isoelectronic helium case of general van der Waals Eq. (16.25) given by Eq. (16.99) also applies to hydrogen-type molecules. Based on symmetry, the molecules at aligned along their semimajor axes, the induces charges act the position of the nuclei at the foci, and the dipole separation is in the direction of the semimajor axes given by the internuclear distance (Eq. (11.204)).

The van der Waals bonding in the hydrogen-type molecules involves hybridizing the $1s$ molecular orbitals (MO) into a $1s^1$ hybridized molecular orbital (HMO) containing two electrons. The total energy of the state is given by the sum over the two electrons given by Eq. (11.241). The sum $E_T\left(H_2\left(1/p\right),1s^1\right)$ is:

$$E_T = -p^2 31.351\, eV - p^3 0.326469\, eV \tag{16.172}$$

The HMO electron energy is equally distributed to each equivalent electron to give the Coulombic energy $E_{Coulomb}\left(H_2(1/p),1s^1\right)$ of the outer electron of the van der Waals bound $H_2(1/p)1s^1$ shell:

$$E_{Coulomb}\left(H_2(1/p),1s^1\right)=\frac{-p^2 31.351\ eV-p^3 0.326469\ eV}{2}$$
$$=-p^2 15.6755\ eV-p^3 0.16323\ eV \tag{16.173}$$

To meet the equipotential condition of the union of the two $H_2(1/p)1s^1$ HOs in a nascent bond, c_2 of Eqs. (15.2-15.5) and Eq. (15.61) for the nascent $H_2(1/p)-H_2(1/p)$-bond MO is given by Eq. (15.75) as the ratio of the valance energy of the $H_2(1/p)$ MO, $E_{IP_1}\left(H_2(1/p)\right)=p^2 15.2171\ eV+p^3 0.207714\ eV$ given by Eq. (11. 244) and the magnitude of $E_{Coulomb}\left(H_2(1/p),1s^1\right)$ (Eq. (16.173)):

$$c_2\left(H_2(1/p)-H_2(1/p),H_2(1/p)1s^1 HMO\right)=\frac{p^2 15.2171\ eV+p^3 0.207714\ eV}{p^2 15.6755\ eV+p^3 0.16323\ eV} \tag{16.174}$$

The opposite charge distributions act as point charges at the foci, the position of the nuclei such that the separation distance is the internuclear distance given by Eq. (11.204).

The van der Waals dipole of $H_2(1/p)$ is calculated by the same method as that of helium using the parameters of Eq. (16.174) and $2c'=\frac{a_0\sqrt{2}}{p}$ (Eq. (11.204)). As in the case with helium, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using the van der Waals dipole of $H_2(1/p)$, the van der Waals energy for a hydrogen type dimer is:

$$E_{van\ der\ Waals}\left(H_2(1/p)\right)=\frac{2\left(\mu_{H_2(1/p)}\right)^2}{4\pi\varepsilon_0\left(r_{H_2(1/p)\cdots H_2(1/p)}\right)^3} \tag{16.175}$$

The dimer interatomic distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.175)) between neighboring dipoles equated to the nascent bond energy. From the energy relationship given by Eq. (16.25) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $H_2(1/p)\cdots H_2(1/p)$ MO can be solved.

PARAMETERS AND ENERGIES DUE TO THE INTERMOLECULAR VAN DER WAALS COHESIVE ENERGIES OF H_2 DIMER

In the case of H_2, $p=1$ such that the parameter c_2 is given by

$$c_2\left(H_2-H_2,H_2 1s^1 HMO\right)=\frac{1^2 15.2171\ eV+1^3 0.207714\ eV}{1^2 15.6755\ eV+1^3 0.16323\ eV}=0.9739 \tag{16.176}$$

Using the parameters of Eq. (16.176) and $2c'=a_0\sqrt{2}$ (Eq. (11.204)), the van der Waals dipole of H_2 is given in Table 16.42.

Table 16.42. The parameters and van der Waals dipole bond moment of the H_2 functional group of hydrogen dimer.

Functional Group	n_1	$(c_1)c_2$	$(C_1)C_2$	$E_B(valence)$	$E_A(valence)$	$\frac{q}{e}$	Bond Length $2c'$ $(\AA)$	Bond Moment μ (D)
H_2	1	0.9739	1	15.4248	15.83901	0.05300	0.748369	0.19053

The van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{H_2}=0.19053\ D=6.35524\ X\ 10^{-31} C\cdot m$ (Table 16.42), the van der Waals energy is:

$$E_{van\ der\ Waals}\left(H_2\right)=\frac{2\left(\mu_{H_2}\right)^2}{4\pi\varepsilon_0\left(r_{H_2\cdots H_2}\right)^3}=\frac{2\left(6.35524\ X\ 10^{-31} C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{H_2\cdots H_2}a_0}{2C_1C_2}}\right)^3} \tag{16.177}$$

The hydrogen dimer intermolecular distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.177)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter c_2 of $H_2 \cdots H_2$ is the same as that of the H_2 dipole, and the reduced mass is $\mu = 1$. The parameters are summarized in Table 16.43 and Eq. (16.178).

Table 16.43. The energy parameters (eV) of the hydrogen dimer functional group ($H_2 \cdots H_2$).

Substitution of the parameters of Table 16.43 and the interatomic cohesive energy of hydrogen dimer (Eq. (16.177)) into Eq. (16.25) with $R = a_{H_2 \cdots H_2}$ gives:

$$\frac{-2\left(6.35524\ X\ 10^{-31} C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{H_2\cdots H_2}a_0}{2(0.5)(0.97385)^{-1}}}\right)^3}$$

$$=\left\{\left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{a_{H_2\cdots H_2}a_0}{2(0.5)(0.97385)^{-1}}}}\left((0.97385)\left(2-\frac{1}{2}\frac{a_0}{a_{H_2\cdots H_2}}\right)\ln\frac{a+\sqrt{\frac{a_{H_2\cdots H_2}a_0}{2(0.5)(0.97385)^{-1}}}}{a-\sqrt{\frac{a_{H_2\cdots H_2}a_0}{2(0.5)(0.97385)^{-1}}}}-1\right)\right)\right.$$

$$\left.\left(1+2\sqrt{\frac{2\hbar\sqrt{(0.5)(0.97385)^{-1}\frac{e^2}{4\pi\varepsilon_o\left(a_{H_2\cdots H_2}\right)^3}}}{m_e c^2}}\right)+\left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{(0.97385)(0.05300e)^2}{8\pi\varepsilon_o\left(a_{H_2\cdots H_2}\right)^3}-\frac{(0.05300e)^2}{8\pi\varepsilon_o\left(a_{H_2\cdots H_2}+\sqrt{\frac{a_{H_2\cdots H_2}a_0}{2(0.5)(0.97385)^{-1}}}\right)^3}}{1}}\right\}$$

(16.178)

wherein (0.05300) is q/e the induced charge from Table 16.42. From the energy relationship given by Eq. (16.178) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $H_2\cdots H_2$ MO can be solved.

The most convenient way to solve Eq. (16.178) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{H_2\cdots H_2}=14.88260a_0=7.87553\ X\ 10^{-10}\ m \tag{16.179}$$

The component energy parameters at this condition are given in Table 16.43. Substitution of Eq. (16.179) into Eq. (16.22) gives

$$c'_{H_2\cdots H_2}=3.80702a_0=2.01459\ X\ 10^{-10}\ m \tag{16.180}$$

and internuclear distance between neighboring H_2 nuclei:

$$2c'_{H_2\cdots H_2}=7.61404a_0=4.02918\ X\ 10^{-10}\ m=4.02918\ \mathring{A} \tag{16.181}$$

The other intermolecular bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.179) and (16.180) into Eq. (16.23) gives

$$b_{H_2\cdots H_2}=c_{H_2\cdots H_2}=14.38744a_0=7.61350\ X\ 10^{-10}\ m \tag{16.182}$$

Substitution of Eqs. (16.179) and (16.180) into Eq. (16.25) gives:

$$e_{H_2\cdots H_2}=0.25580 \tag{16.183}$$

Using Eqs. (16.177) and (16.181), the van der Waals energy of the hydrogen dimer is:

$$E_{van\ der\ Waals}\left([H_2]_2\right)=0.00069\ eV\left(5.59\ cm^{-1}\right) \tag{16.184}$$

The experimental D_0 is shown in Figure of Ref. [124], [125] is:

$$D_0=5.6\ cm^{-1} \tag{16.185}$$

From Table 16.43, the hydrogen dimer vibrational energy $\bar{E}_{Kvib}\ (eV)$ that matches the experimental dimer spectrum [126] is

$$\bar{E}_{Kvib}\ (eV)=0.00028\ eV\left(2.3\ cm^{-1}\right) \tag{16.186}$$

PARAMETERS AND ENERGIES DUE TO THE INTERMOLECULAR VAN DER WAALS COHESIVE ENERGIES OF SOLID H_2

The minimum-energy packing of H_2 dipoles is face-centered cubic also called cubic close packing. In this case, each H_2 molecule has 12 nearest neighbors and the angle between the aligned dipoles is $\frac{\pi}{4}$ radians. As in the case with hydrogen dimer, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{H_2}=0.19053\ D=6.35524\ X\ 10^{-31} C\cdot m$ (Table 16.42), the van der Waals energy is:

$$E_{van\ der\ Waals}\left(H_2\right)=12\frac{2\left(\mu_{H_2}\right)^2}{4\pi\varepsilon_0\left(r_{H_2\cdots H_2}\right)^3}\cos\left(\frac{\pi}{4}\right)=\frac{24\left(6.35524\ X\ 10^{-31}C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{H_2\cdots H_2}a_0}{2C_1C_2}}\right)^3}\cos\left(\frac{\pi}{4}\right) \tag{16.187}$$

The hydrogen dimer intermolecular distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.187)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter c_2 of $H_2\cdots H_2$ is the same as that of the H_2 dipole, and the reduced mass is $\mu=1$. The parameters are summarized in Table 16.44 and Eq. (16.188).

Substitution of the parameters of Table 16.43 and the interatomic cohesive energy of solid hydrogen (Eq. (16.187)) into Eq. (16.25) with $R=a_{H_2\cdots H_2}$ gives:

$$\frac{-24\left(6.35524\ X\ 10^{-31} C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{H_2\cdots H_2}a_0}{2(0.5)(0.97385)^{-1}}}\right)^3}\cos\left(\frac{\pi}{4}\right)$$

$$=\left\{\left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{a_{H_2\cdots H_2}a_0}{2(0.5)(0.97385)^{-1}}}}\left((0.97385)\left(2-\frac{1}{2}\frac{a_0}{a_{H_2\cdots H_2}}\right)\ln\frac{a+\sqrt{\frac{a_{H_2\cdots H_2}a_0}{2(0.5)(0.97385)^{-1}}}}{a-\sqrt{\frac{a_{H_2\cdots H_2}a_0}{2(0.5)(0.97385)^{-1}}}}-1\right)\right)\right.$$

$$\left.\left(1+2\sqrt{\frac{2\hbar\sqrt{\frac{(0.5)(0.97385)^{-1}\frac{e^2}{4\pi\varepsilon_o\left(a_{H_2\cdots H_2}\right)^3}}{m_e}}{m_e c^2}}\right)+\left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{(0.97385)(0.05300e)^2}{8\pi\varepsilon_o\left(a_{H_2\cdots H_2}\right)^3}-\frac{(0.05300e)^2}{8\pi\varepsilon_o\left(a_{H_2\cdots H_2}+\sqrt{\frac{a_{H_2\cdots H_2}a_0}{2(0.5)(0.97385)^{-1}}}\right)^3}}{1}}\right\}$$

(16.188)

wherein (0.05300) is q/e the induced charge from Table 16.42. From the energy relationship given by Eq. (16.188) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $H_2\cdots H_2$ MO can be solved.

The most convenient way to solve Eq. (16.188) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{H_2\cdots H_2}=14.89100a_0=7.87998\ X\ 10^{-10}\ m \tag{16.189}$$

The component energy parameters at this condition are given in Table 16.44. Substitution of Eq. (16.189) into Eq. (16.22) gives

$$c'_{H_2\cdots H_2}=3.80810a_0=2.01516\ X\ 10^{-10}\ m \tag{16.190}$$

and internuclear distance between neighboring H_2 nuclei:

$$2c'_{H_2\cdots H_2}=7.61619a_0=4.03031\ X\ 10^{-10}\ m=4.03031\ \mathring{A} \tag{16.191}$$

The other intermolecular bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.189) and (16.190) into Eq. (16.23) gives

$$b_{H_2\cdots H_2}=c_{H_2\cdots H_2}=14.39584a_0=7.61795\ X\ 10^{-10}\ m \tag{16.192}$$

Substitution of Eqs. (16.189) and (16.190) into Eq. (16.25) gives:

$$e_{H_2\cdots H_2}=0.25573 \tag{16.193}$$

A convenient method to calculate the lattice energy is to determine the electric field in solid molecular hydrogen having an electric polarization density corresponding to the aligned dipoles moments, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic form of Gauss' equation. Substitution of the density of solid hydrogen $\rho=\frac{0.086\ g}{1\ X\ 10^{-6}\ m^3}$ [127], the $MW=2.016\ g/mole$, $N_A=6.0221415\ X\ 10^{23}\ molecules/mole$, and the H_2 dipole moment given in Table 16.42 into Eq. (16.53) gives:

$$U(H_2)=\frac{-2\left(\mu_{H_2}\right)^2\frac{\rho_{solid\ H_2}}{MW}N_A}{3\varepsilon_0}$$

$$=\frac{-2\left(6.35524\ X\ 10^{-31} C\cdot m\right)^2\frac{\frac{0.086\ g}{1\ X\ 10^{-6}\ m^3}}{2.016 g/mole}6.0221415\ X\ 10^{23}\ molecules/mole}{3\varepsilon_0}$$

$$=-0.00488\ eV\ \left(-0.470\ kJ/mole\right)$$

$$U(Ne)=\frac{-2(\mu_{Ne})^2\frac{\rho_{solid\ Ne}}{MW}N_A}{3\varepsilon_0}$$

$$=\frac{-2\left(1.08554\ X\ 10^{-30}C\cdot m\right)^2\frac{\frac{1.433\ g}{1\ X\ 10^{-6}\ m^3}}{20.179 g/mole}6.0221415\ X\ 10^{23}\ molecules/mole}{3\varepsilon_0} \tag{16.194}$$

$$=-0.02368\ eV\ \ (-2.285\ kJ/mole)$$

$U(H_2)$ is also the negative of $E_{van\ der\ Waals}$, the van der Waals energy per H_2 molecule:

$$E_{van\ der\ Waals}(solid\ H_2/H_2)=0.00488\ eV=0.470\ kJ/mole \tag{16.195}$$

The experimental van der Waals energy calculated from the heat of vaporization and fusion per hydrogen molecule [128] is

$$\begin{aligned}E_{van\ der\ Waals}(solid\ H_2)&=E_{vapor}+E_{fusion}\\&=0.44936\ kJ/mole+0.05868\ kJ/mole\\&=0.50804\ kJ/mole\end{aligned} \tag{16.196}$$

PARAMETERS AND ENERGIES DUE TO THE INTERMOLECULAR VAN DER WAALS COHESIVE ENERGIES OF $H_2(1/4)$ DIMER

In the case of H_2, $p=4$ such that the parameter c_2 is given by

$$\begin{aligned}c_2\left(H_2(1/4)-H_2(1/4),H_2(1/4)1s^1HMO\right)&=\frac{4^2 15.2171\ eV+4^3 0.207714\ eV}{4^2 15.6755\ eV+4^3 0.16323\ eV}\\&=0.9828\end{aligned} \tag{16.197}$$

Using the parameters of Eq. (16.197) and $2c'=a_0\frac{\sqrt{2}}{4}$ (Eq. (11.204)), the van der Waals dipole of $H_2(1/4)$ is given in Table 16.45.

Table 16.45. The parameters and van der Waals dipole bond moment of the $H_2(1/4)$ functional group of hydrogen dimer.

Functional Group	n_1	(c_1) c_2	(C_1) C_2	$E_B(valence)$	$E_A(valence)$	$\frac{q}{e}$	Bond Length $2c'$ (Å)	Bond Moment μ (D)
$H_2(1/4)$	1	0.9828	1	256.767	261.255	0.03466	0.187092	0.03114

The van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{H_2(1/4)}=0.03114\ D=1.03885\ X\ 10^{-31}C\cdot m$ (Table 16.45), the van der Waals energy is:

$$E_{van\ der\ Waals}\left(H_2(1/4)\right)=\frac{2\left(\mu_{H_2(1/4)}\right)^2}{4\pi\varepsilon_0\left(r_{H_2(1/4)\cdots H_2(1/4)}\right)^3}=\frac{2\left(1.03885\ X\ 10^{-31}C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{H_2(1/4)\cdots H_2(1/4)}a_0}{2C_1C_2}}\right)^3} \tag{16.198}$$

The molecular hydrino dimer intermolecular distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.198)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter c_2 of $H_2(1/4)\cdots H_2(1/4)$ is the same as that of the $H_2(1/4)$ dipole, and the reduced mass is $\mu=1$. The parameters are summarized in Table 16.46 and Eq. (16.199).

Table 16.46. The energy parameters (eV) of the hydrogen dimer functional group ($H_2(1/4)\cdots H_2(1/4)$).

Substitution of the parameters of Table 16.46 and the interatomic cohesive energy of hydrogen dimer (Eq. (16.198)) into Eq. (16.25) with $R = a_{H_2(1/4)\cdots H_2(1/4)}$ gives:

$$\frac{-2\left(1.03885\ X\ 10^{-31} C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{H_2(1/4)\cdots H_2(1/4)}a_0}{2(0.5)(0.9828)^{-1}}}\right)^3} = \left\{\left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{a_{H_2(1/4)\cdots H_2(1/4)}a_0}{2(0.5)(0.9828)^{-1}}}}\right)\left((0.9828)\left(2-\frac{1}{2}\frac{a_0}{a_{H_2(1/4)\cdots H_2(1/4)}}\right)\right)\left(\ln\frac{a+\sqrt{\frac{a_{H_2(1/4)\cdots H_2(1/4)}a_0}{2(0.5)(0.9828)^{-1}}}}{a-\sqrt{\frac{a_{H_2(1/4)\cdots H_2(1/4)}a_0}{2(0.5)(0.9828)^{-1}}}}-1\right)\right\}$$
$$\left\{\left(1+2\sqrt{\frac{2\hbar\sqrt{\frac{(0.5)(0.9828)^{-1}\frac{e^2}{4\pi\varepsilon_o\left(a_{H_2(1/4)\cdots H_2(1/4)}\right)^3}}{m_e}}}{m_e c^2}}\right)+\left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{(0.9828)(0.03466e)^2}{8\pi\varepsilon_o\left(a_{H_2(1/4)\cdots H_2(1/4)}\right)^3}-\frac{(0.03466e)^2}{8\pi\varepsilon_o\left(a_{H_2(1/4)\cdots H_2(1/4)}+\sqrt{\frac{a_{H_2(1/4)\cdots H_2(1/4)}a_0}{2(0.5)(0.9828)^{-1}}}\right)^3}}{1}}\right\} \quad (16.199)$$

wherein (0.03466) is q/e the induced charge from Table 16.45. From the energy relationship given by Eq. (16.199) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $H_2(1/4)\cdots H_2(1/4)$ MO can be solved.

The most convenient way to solve Eq. (16.199) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{H_2(1/4)\cdots H_2(1/4)_2} = 3.83931 a_0 = 2.03168\ X\ 10^{-10}\ m \quad (16.200)$$

The component energy parameters at this condition are given in Table 16.46. Substitution of Eq. (16.200) into Eq. (16.22) gives

$$c'_{H_2(1/4)\cdots H_2(1/4)_2} = 0.97126 a_0 = 5.13967\ X\ 10^{-11}\ m \quad (16.201)$$

and internuclear distance between neighboring H_2 nuclei:

$$2c'_{H_2(1/4)\cdots H_2(1/4)_2} = 1.94251 a_0 = 1.02793\ X\ 10^{-10}\ m = 1.02793\ \text{Å} \quad (16.202)$$

The other intermolecular bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.200) and (16.201) into Eq. (16.23) gives

$$b_{H_2(1/4)\cdots H_2(1/4)_2} = c_{H_2(1/4)\cdots H_2(1/4)_2} = 3.71443 a_0 = 1.96559\ X\ 10^{-10}\ m \quad (16.203)$$

Substitution of Eqs. (16.200) and (16.201) into Eq. (16.25) gives:

$$e_{H_2(1/4)\cdots H_2(1/4)_2} = 0.25298 \quad (16.204)$$

Using Eqs. (16.198) and (16.202), the van der Waals energy of the hydrogen dimer is:

$$E_{van\ der\ Waals}\left([H_2(1/4)]_2\right) = 0.00111\ eV\left(8.991\ cm^{-1}\right) \quad (16.205)$$

PARAMETERS AND ENERGIES DUE TO THE INTERMOLECULAR VAN DER WAALS COHESIVE ENERGIES OF SOLID $H_2(1/4)$

The minimum-energy packing of $H_2(1/4)$ dipoles is face-centered cubic also called cubic close packing. In this case, each $H_2(1/4)$ molecule has 12 nearest neighbors and the angle between the aligned dipoles is $\frac{\pi}{4}$ radians. As in the case with $H_2(1/4)$ dimer, the van der Waals energy is the potential energy between interacting neighboring induced dipoles. Using $\mu_{H_2(1/4)} = 0.03114\ D = 1.03885\ X\ 10^{-31} C\cdot m$ (Table 16.45), the van der Waals energy is:

$$E_{van\ der\ Waals}\left(H_2(1/4)\right)=12\frac{2\left(\mu_{H_2(1/4)}\right)^2}{4\pi\varepsilon_0\left(r_{H_2(1/4)\cdots H_2(1/4)}\right)^3}\cos\left(\frac{\pi}{4}\right)$$
$$=\frac{24\left(1.03885\ X\ 10^{-31}C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{H_2(1/4)\cdots H_2(1/4)}a_0}{2C_1C_2}}\right)^3}\cos\left(\frac{\pi}{4}\right) \quad (16.206)$$

The hydrogen dimer intermolecular distance is calculated using Eq. (16.25) with the van der Waals energy (Eq. (16.206)) between neighboring dipoles equated to the nascent bond energy. The energy matching parameter c_2 of $H_2(1/4)\cdots H_2(1/4)$ is the same as that of the $H_2(1/4)$ dipole, and the reduced mass is $\mu=1$. The parameters are summarized in Table 16.47 and Eq. (16.207).

$E_{T(Group)}\ (eV)$	-0.00946

Substitution of the parameters of Table 16.47 and the interatomic cohesive energy of solid hydrogen (Eq. (16.206)) into Eq. (16.25) with $R = a_{H_2(1/4)\cdots H_2(1/4)}$ gives:

$$\frac{-24\left(1.03885\ X\ 10^{-31} C\cdot m\right)^2}{4\pi\varepsilon_0\left(2\sqrt{\frac{a_{H_2(1/4)\cdots H_2(1/4)}a_0}{2(0.5)(0.9828)^{-1}}}\right)^3}\cos\left(\frac{\pi}{4}\right)$$

$$= \left\{ \left(\frac{-e^2}{8\pi\varepsilon_0\sqrt{\frac{a_{H_2(1/4)\cdots H_2(1/4)}a_0}{2(0.5)(0.9828)^{-1}}}} \left((0.9828)\left(2-\frac{1}{2}\frac{a_0}{a_{H_2(1/4)\cdots H_2(1/4)}}\right) \right) \right) \right.$$

$$\left. \left(1+2\sqrt{\frac{2\hbar\sqrt{(0.5)(0.9828)^{-1}\frac{e^2}{4\pi\varepsilon_o\left(a_{H_2(1/4)\cdots H_2(1/4)}\right)^3}}}{m_e c^2}} \right) + \left(\frac{1}{2}\right)\hbar\sqrt{\frac{\frac{(0.9828)(0.03466e)^2}{8\pi\varepsilon_o\left(a_{H_2(1/4)\cdots H_2(1/4)}\right)^3} - \frac{(0.03466e)^2}{8\pi\varepsilon_o\left(a_{H_2(1/4)\cdots H_2(1/4)}+\sqrt{\frac{a_{H_2(1/4)\cdots H_2(1/4)}a_0}{2(0.5)(0.9828)^{-1}}}\right)^3}}{1}} \right\} \tag{16.207}$$

wherein (0.03466) is q/e the induced charge from Table 16.42. From the energy relationship given by Eq. (16.207) and the relationships between the axes given by Eqs. (16.22-16.24), the dimensions of the $H_2(1/4)\cdots H_2(1/4)$ MO can be solved.

The most convenient way to solve Eq. (16.207) is by the reiterative technique using a computer. The result to within the round-off error with five-significant figures is:

$$a_{H_2(1/4)\cdots H_2(1/4)} = 3.83819 a_0 = 2.03108\ X\ 10^{-10}\ m \tag{16.208}$$

The component energy parameters at this condition are given in Table 16.47. Substitution of Eq. (16.208) into Eq. (16.22) gives

$$c'_{H_2(1/4)\cdots H_2(1/4)_2} = 0.97111 a_0 = 5.13891\ X\ 10^{-11}\ m \tag{16.209}$$

and internuclear distance between neighboring $H_2(1/4)$ nuclei:

$$2c'_{H_2(1/4)\cdots H_2(1/4)} = 1.94223 a_0 = 1.02778\ X\ 10^{-10}\ m = 1.02778\ \mathring{A} \tag{16.210}$$

The other intermolecular bond MO parameters can also be determined by the relationships among the parameters. Substitution of Eqs. (16.208) and (16.209) into Eq. (16.23) gives

$$b_{H_2(1/4)\cdots H_2(1/4)_2} = c_{H_2(1/4)\cdots H_2(1/4)_2} = 3.71330 a_0 = 1.96499\ X\ 10^{-10}\ m \tag{16.211}$$

Substitution of Eqs. (16.208) and (16.209) into Eq. (16.25) gives:

$$e_{H_2(1/4)\cdots H_2(1/4)_2} = 0.25301 \tag{16.212}$$

A convenient method to calculate the lattice energy is to determine the electric field in solid molecular hydrogen having an electric polarization density corresponding to the aligned dipoles moments, and in turn, the energy can be calculated from the energy of each dipole in the corresponding field using the electrostatic form of Gauss' equation. The $H_2(1/4)$ number density of solid $H_2(1/4)$ $\tilde{N}$ is given by the 4, the number of $H_2(1/4)$ molecules per unit cell divided by the volume of the face centered cubic cell. Using the neighbor internuclear distance $2c'_{H_2(1/4)\cdots H_2(1/4)}$ (Eq. (16.210)) as the length of the unit cell, $\tilde{N}$ can be approximated by

$$\tilde{N} = \frac{4}{\left(2c'_{H_2(1/4)\cdots H_2(1/4)}\right)^3} = \frac{4}{\left(1.02778\ X\ 10^{-10}\ m\right)^3} = 3.684\ X\ 10^{30}\ H_2(1/4) m^{-3} \tag{16.213}$$

Substitution of number density of solid $H_2(1/4)$ $\tilde{N}$ given by Eq. (16.213) and the $H_2(1/4)$ dipole moment given in Table 16.45 into Eq. (16.53) gives:

$$U\left(H_2(1/4)\right) = \frac{-2\left(\mu_{H_2(1/4)}\right)^2 \tilde{N}}{3\varepsilon_0}$$
$$= \frac{-2\left(1.03885\ X\ 10^{-31} C\cdot m\right)^2 3.684\ X\ 10^{30}\ H_2(1/4) m^{-3}}{3\varepsilon_0} \quad (16.214)$$
$$= -0.01869\ eV\ \left(-1.803\ kJ/mole\right)$$

$U\left(H_2(1/4)\right)$ is also the negative of $E_{van\ der\ Waals}$, the van der Waals energy per $H_2(1/4)$ molecule:

$$E_{van\ der\ Waals}\left(solid\ H_2(1/4)/H_2(1/4)\right) = 0.01869\ eV\ \left(1.803\ kJ/mole\right) \quad (16.215)$$

PARAMETERS AND MAGNETIC ENERGIES DUE TO THE SPIN MAGNETIC MOMENT OF $H_2(1/4)$

Molecular hydrino $H_2(1/p)$ comprises (i) two electrons bound in a minimum energy, equipotential, prolate spheroidal, two-dimensional current membrane comprising a molecular orbital (MO), (ii) two $Z=1$ nuclei such as two protons at the foci of the prolate spheroid, and (iii) a photon wherein the photon equation of each state is different from that of an excited H_2 state given in the Excited States of the Hydrogen Molecule section, in that the photon increases the central field by an integer rather than decreasing the central prolate spheroidal field to that of a reciprocal integer of the fundamental charge at each nucleus centered on the foci of the spheroid, and the electrons of $H_2(1/p)$ are paired in the same shell at the same position ξ versus being in separate ξ positions. The interaction of the hydrino state photon electric field with each electron gives rise to a nonradiative radial monopole such that the state is stable. In contrast, by the same mechanism, the excited H_2 state photon gives rise to a radiative radial dipole at the outer excited state electron resulting in the state being unstable to radiation. For exited states, the photon electric field comprises a prolate spheroidal harmonic in space and time that modulates the constant prolate spheroidal current of the outer electron in-phase. The former corresponds to orbital angular momentum and the latter corresponds to spin angular momentum. Due to the unique stable state of molecular hydrino comprising two nonradiative electrons in a single MO, the nature of the trapped photon field, the nature of the vector photon propagation inside the molecular hydrino serving as a resonator cavity, and the nature of the electron currents are unique.

Consider the formation of a nonradiative state H_2 molecule from two non-radiative $n=1$ state H atoms requiring the bond energy to be removed by a third body collision:

$$H + H + M \rightarrow H_2 + M^* \quad (16.216a)$$

wherein M^* denotes the third body in an energetic state[2]. Molecular hydrino may form by the same nonradiative mechanism wherein, hydrino atoms and hydrino molecules comprise an additional photon component of the central field that is nonradiative by virtue of being equivalent to an integer multiple of the central field of a proton at the origin and at each focus of the prolate spheroid MO, respectively. The combination of two electrons into a single molecular orbital while maintaining the radiationless integer photonic central field gives rise to the special case of a doublet MO state in molecular hydrino rather than a singlet state. The singlet state is nonmagnetic; whereas, the doublet state has a net magnetic moment of a Bohr magneton μ_B.

Specifically, the basis element of the current of each hydrogen-type atom is a great circle as shown in the Generation of the Atomic Orbital-CVFS section, and the great circle current basis elements transition to elliptic current basis elements in hydrogen-type molecules as shown in the Force Balance of Hydrogen-Type Molecules section. As shown in the Equation of the Electric Field inside the Atomic Orbital section, (i) photons carry electric field and comprise closed field line loops, (ii) a hydrino or a molecular hydrino each comprises a trapped photon wherein the photon field-line loops each travel along a mated great circle or elliptic current loop basis element in the same vector direction, (iii) the direction of each field line increases in the direction perpendicular to the propagation direction with relative motion as required by special relativity, and (iv) since the linear velocity of each point along a field line loop of a trapped photon is light speed c, the electric field direction relative to the laboratory frame is purely perpendicular to its mated current loop and it exists only at $\delta(r-r_n)$. The paired electrons of the hydrogen molecular orbital comprise a singlet state having no net magnetic moment. However, the photon field lines of two

---

[2] The hydrino molecule comprises two hydrogen isotope nuclei and two electrons in a single molecular orbital (MO). Uniquely the MO comprises a paired and unpaired electron (Parameters and Magnetic Energies Due to the Spin Magnetic Moment of $H_2(1/4)$ section). To conserve spin angular momentum during the formation of a bond between two hydrino atoms, the bond energy must be released as a neutrino such as an electron neutrino of spin ½ that serves the function of the third body of M^* Eq. (16.216a):

$$H(1/p) + H(1/p) \rightarrow H_2(1/p) + \upsilon_e \quad (16.216b)$$

Specifically, a neutrino comprises a photon having $\frac{\hbar}{2}$ angular momentum in its electric and magnetic fields (Neutrinos section). During the reaction of Eq. (16.216b), the angular momentum of the reactants is conserved in the products wherein each of the two reacting hydrino atoms are electron spin ½, and the product molecular hydrino and electron neutrino are also each spin ½. The neutrino emission reaction (Eq. (16.216b)) may be exploited for communication (e.g. a neutrino telecommunication system).

hydrino atoms that superimpose during the formation of a molecular hydrino can only propagate in one direction to avoid cancellation and give rise to a central field to provide force balance between the centrifugal and central forces (Eq. (11.200)). This special case gives rise to a doublet state in molecular hydrino.

The MO may be treated as a linear combination of the great ellipses that comprise the current density function of each electron as given in the Generation of the Orbitsphere-CVFS section and the Force Balance of Hydrogen-Type Molecules section. To meet the boundary conditions that each corresponding photon is matched in direction with each electron current and that the electron angular momentum is $\hbar$ are satisfied, one half of electron 1 and one half of electron 2 may be spin up and matched with the two photons of the two electrons on the MO, and the other half of electron 1 may be spin up and the other half of electron 2 may be spin down such that one half of the currents are paired and one half of the currents are unpaired. Thus, the spin of the MO is $\frac{1}{2}\left(\uparrow\uparrow+\downarrow\uparrow\right)$ where each arrow designates the spin vector of one electron. The two photons that bind the two electrons in the molecular hydrino state are phase-locked to the electron currents and circulate in opposite directions. Given the indivisibility of each electron and the condition that the MO comprises two identical electrons, the force of the two photons is transferred to the totality of the electron MO comprising a linear combination of the two identical electrons to satisfy Eq. (11.200). The resulting angular momentum and magnetic moment of the unpaired current density are $\hbar$ and a Bohr magneton μ_B, respectively.

Due to its unpaired electron, molecular hydrino is electron paramagnetic resonance (EPR) spectroscopy active. Moreover, due to the unpaired electron in a common molecular orbital with a paired electron, the EPR spectrum is uniquely characteristic of and identifies molecular hydrino as shown *infra*. As given in the Electron g Factor section, flux is linked by an unpaired electron in quantized units of the fluxon or magnetic flux quantum $\frac{h}{2e}$. The electric energy, the magnetic energy, and the dissipated energy of a fluxon treading the atomic orbital given by Eqs. (1.226 -1.227) is

$$\Delta E_{mag\ g}^{spin}=2\left(1+\frac{\alpha}{2\pi}+\frac{2}{3}\alpha^2\left(\frac{\alpha}{2\pi}\right)-\frac{4}{3}\left(\frac{\alpha}{2\pi}\right)^2\right)\mu_B B=g\mu_B B \tag{16.217}$$

In the case of the molecular hydrino, the unpaired electron is a linear combination of two electrons of the MO wherein one half of the current density is paired, and one half is unpaired. The fluxon links both interlocked electrons such that the contribution of the flux linkage terms are doubled. The corresponding g factor is

$$g_{H_2(1/p)}=2\left(1+2\left(\frac{\alpha}{2\pi}+\frac{2}{3}\alpha^2\left(\frac{\alpha}{2\pi}\right)-\frac{4}{3}\left(\frac{\alpha}{2\pi}\right)^2\right)\right)=2.0046386 \tag{16.218}$$

The energy between parallel and antiparallel levels of the unpaired electron in an applied magnetic field is

$$\Delta E_{mag\ 2.0046}^{spin}=g_{H_2(1/p)}\mu_B B=2.0046386\mu_B B \tag{16.219}$$

The result of Eq. (16.218) was confirmed wherein the electron paramagnetic resonance peak was observed with g factor of 2.00445 [131].

Molecular hydrino comprises a linear combination of an unpaired and a paired electron in a common prolate spheroidal molecular orbital (MO) wherein ellipsoidal current elements alternate in pairs of contiguous parallel and antiparallel currents. Consider the designation of the prolate spheroidal MO wherein the y and z-axes are semiminor axes and the x-axis is the semimajor axis. The resulting current density comprises a prolate spheroid possessing $\frac{\hbar}{2}$ of angular momentum along either the +z-axis or –z-axis and $\frac{\hbar}{4}$ along each of the +y and –y-axes as shown in Figure 11.4 wherein the unpaired-paired intrinsic current density may occupy two degenerate distributions about either the +z-axis or –z-axis. The application of a magnetic field lifts the degeneracy. The semimajor or x-axis of the molecular hydrino aligns parallel or antiparallel to an applied magnetic field with capture of a photon of the Larmor frequency corresponding to the applied field-electron spin interaction energy $E_{\uparrow\uparrow/\downarrow\uparrow}$ given by the Bohr magneton μ_B times the applied flux B:

$$E_{\uparrow\uparrow/\downarrow\uparrow}=\mu_B B \tag{16.220}$$

The resulting cylindrical rotation of the MO current about the semimajor axis gives rise to $\hbar$ of angular momentum along either the +x or –x-axis (Figure 11.4) and causes the spin current vectors in the transverse plane containing the semiminor axes to average to zero. A 180° electron spin flip transition along the semimajor axis may occur with the absorption of a resonant microwave photon having the energy given by Eqs. (16.217-16.219). The $\hbar$ of angular momentum of the spin flip photon aligns along either the +z or –z-axis in the transverse plane wherein the unpaired current $\frac{\hbar}{2}$ of angular momentum along the either the +z-axis or –z-axis quantizes the orientation of spin flip photon angular momentum. In the case that the angular momentum of the spin flip photon is opposite that of the unpaired current, the unpaired current also flips its orientation with a concomitant flip of the corresponding angular momentum by 180° in the transverse plane. The semiminor axis spin flip transition lifts the degeneracy of the semimajor axis spin flip transition due to an interaction of the paired and unpaired current of the MO. The

three sources of splitting of the spin flip transition are considered: (i) the energy of interaction of the internal magnetic field of the electron MO on the proton magnetic moments, (ii) the energy of interaction of the transition between nuclear spin isomer states on the spin of the electron MO, and (iii) the coupling energy between the spin unpaired electro and the spin paired electron of the $H_2(1/4)$ electron MO.

Hydrogen-type molecules comprise a proton at each focus of the prolate spheroid molecular orbital, each with nuclear spin and a corresponding magnetic dipole moment of μ_P. Consider that effect on the protons when a magnetic field is applied along the semimajor axis, the x-axis, that excites the Larmor precession of the unpaired electron of $H_2(1/p)$ to give rise to an electron spin magnetic moment of a Bohr magneton also aligned along the semimajor axis. The intrinsic electron spin vectors along the two transverse semiminor axes, the y-axis and the z-axis, as shown in Figure 11.4 rotate around the applied magnetic field and the electron spin magnetic moment at the Larmor frequency given by Eq. (1.227). The magnetic field inside the ellipsoidal MO, $\mathbf{H}_x^-$, (Eq. (12.31)) is:

$$B_x^- = \mu_0 \frac{e\hbar}{2m_e} \frac{1}{a^3\left(1-\frac{b^2}{a^2}\right)^{3/2}} \left(2\sqrt{1-\frac{b^2}{a^2}} + \ln \frac{1+\sqrt{1-\frac{b^2}{a^2}}}{1-\sqrt{1-\frac{b^2}{a^2}}} \right) \tag{16.221}$$

Substitution of the $H_2(1/4)$ semimajor axis a (Eq. (11.202)) and the $H_2(1/4)$ semiminor axis b (Eq. (11.205)) into Eq. (16.221) gives

$$B_x^- = 4.52\,X10^4\ T \tag{16.222}$$

This large electrodynamic field aligns parallel or antiparallel to the applied field corresponding to the direction of the Larmor electron magnetic moment. However, this electrodynamic field is transverse to the vector direction of the proton magnetic moments that must align along the direction of the magnetostatic intrinsic spin as a condition of the formation and energy stability of the $H_2(1/4)$ molecule. Thus, the nuclear magnetic moments align in the transverse plane, the yz-plane that is perpendicular to three-semimajor axis magnetic components: (i) the applied magnetic field that excites the Larmor rotation, (ii) the electron spin magnetic moment, and (iii) the electrodynamic magnetic field of the electron's Larmor rotation. The intrinsic electron spin vectors along the transverse two semiminor axes, the y-axis and the z-axis, (Figure 11.4) rotate around these three-semimajor axis magnetic components at the Larmor frequency given by Eq. (1.227). Since the nuclear magnetic moments are transverse to the three-semimajor axis magnetic components, and the Larmor-frequency rotation causes the intrinsic electron spin magnetic interaction with the nuclear spins to average to zero, the nuclear magnetic moments do not interact with the three-semimajor axis magnetic components. Then, the energy contribution of the nuclear magnetic moments to an electron spin transition depends only on the mutual interaction of the nuclear magnetic moments.

Next, the interaction between the proton nuclear magnetic moments resulting in the splitting of the quantized energy levels of the electron spin transition by the energy corresponding to the interaction is considered. In general, the potential energy of interaction $E_{mag\ dipole}$ of two quantized magnetic dipoles $\mathbf{m}_1$ and $\mathbf{m}_2$ separated by a distance $|\mathbf{r}|$ is given by

$$E_{mag\ dipole} = -\frac{\mu_0}{4\pi|\mathbf{r}|^3}\left(3(\mathbf{m}_1\cdot\hat{\mathbf{r}})(\mathbf{m}_2\cdot\hat{\mathbf{r}}) - \mathbf{m}_1\cdot\mathbf{m}_2\right) \tag{16.223}$$

where μ_0 is the permeability of free space and $\hat{\mathbf{r}}$ is a unit vector parallel to the line joining the centers of the two dipoles. The energy is decreased in the case of antiparallel interacting magnetic moments, and the energy is increased in the case of parallel magnetic moments. Consider the splitting energy of interaction with two parallel-aligned nuclear magnetic moments. With the substitution of the proton magnetic moment μ_P for each parallel-aligned nuclear magnetic moment and the $H_2(1/4)$ internuclear separation given by Eq. (11.204) for $|\mathbf{r}|$ into Eq. (16.223), the energy $E_{P\ mag\ e\text{-}dipole}$ to flip the spin direction of one proton magnetic moment of $H_2(1/4)$ relative to the other is

$$E_{P\ mag\ e\text{-}dipole} = \frac{2\mu_0\mu_P^2}{4\pi r^3} = \frac{\mu_0\left(1.41060671X10^{-26}JT^{-1}\right)^2}{2\pi\left(2\frac{a_0}{4\sqrt{2}}\right)^3} = \frac{\mu_0\left(1.41060671X10^{-26}JT^{-1}\right)^2}{2\pi\left(1.870924X10^{-11}m\right)^3} \tag{16.224}$$

$$= 6.077X10^{-27}\ J = 3.793X10^{-8}\ eV = 9.171X10^{-3}\ GHz$$

In order for this ortho-para nuclear spin isomer energy of Eq. (16.224) to split the electron spin transition, there must be a coupling mechanism between the nuclear and electron spins. Since the electron spin vector is along the semimajor axis, and the proton spins are transversely oriented in the plane containing the semiminor axes, there is no direct coupling mechanism. Moreover, the flux change inside of the electron MO due to the transition of the nuclear spin isomer state corresponding to Eq. (16.224) has an insignificant effect on the spin transition energy as shown by flux linkage terms of Eq. (16.217). Since the spin

transition is independent of the nuclear spin transition, the electron spin transition leaves the ortho or para nuclear spin state of $H_2(1/4)$ unchanged, and there is no nuclear spin state energy splitting.

Consider the third electron spin splitting mechanism regarding the coupling energy of the spin unpaired and paired electrons of the electron MO. The semiminor axis spin flip transition lifts the degeneracy of the semimajor axis spin flip transition due to an interaction of the paired and unpaired current of the MO. The magnetic field of the unpaired electron induces a diamagnetic current in the paired electron. The resulting magnetic moment that shifts the spin flip transition energy is opposite that of the spin magnetic moment and proportionally much smaller. In addition to the intrinsic relative motion of the linear combination of the paired and unpaired electron currents of $H_2(1/4)$ and the rotation of the electron MO about the semimajor axis corresponding to electron spin along this axis, the paired and unpaired electrons may rotate relative to each other during a spin transition similar to the case of excited-state H_2 as given in the Excited States of the Hydrogen Molecule section. The relative rotation is quantized in terms of m integer units of $\hbar$ in opposite directions wherein the magnetic moments cancel, but the relativistic effect gives rise to a corresponding electron spin-orbital coupling quantum number m. The unpaired-paired coupling or spin-orbital coupling energy is given as the diamagnetic moment times the magnetic flux of the unpaired electron. Since flux is linked by an unpaired electron in units of the magnetic flux quantum, the spin-orbital coupling energy $E_{S/O}$ between two magnetic moments of $H_2(1/4)$ given by Eq. (2.194) can be expressed as:

$$E_{S/O} = \chi_m m\left[\frac{1}{\left(4\sqrt{2}\right)^{-3}}\alpha^5(2\pi)^2 m_e c^2\sqrt{\frac{3}{4}}\right] \tag{16.225}$$

wherein the semiminor radius of the $H_2(1/4)$ MO is given by Eq. (11.205) with $p=4$ and χ_m is the magnitude of the diamagnetic susceptibility of the paired electron given by Eq. (11.416):

$$\begin{aligned}\chi_m &= \alpha\frac{\Delta B_T}{B}\sqrt{\frac{3}{4}} = \alpha\mu_0\left(4-\sqrt{2}\ln\frac{\sqrt{2}+1}{\sqrt{2}-1}\right)\frac{pe^2}{36a_0 m_e}\left(1+p\alpha^2\right)\sqrt{\frac{3}{4}}\\ &= \alpha\left(p28.01+p^2 1.49\ X\ 10^{-3}\right)\sqrt{\frac{3}{4}}ppm = 7.0821\ X\ 10^{-7}\end{aligned} \tag{16.226}$$

In the case of spin-orbital coupling involving the intrinsic spin of $\frac{\hbar}{2}$, the electron spin-orbital coupling quantum number m is $m = 1/2$. Additional states arise due to the relative motion of the two electrons of the $H_2(1/4)$ MO. Consider the case of H_2 excited states given in the Excited States of the Hydrogen Molecule section wherein the relative rotational motion of the two excited state electrons corresponds to the quantum number m being a positive or negative integer such that net relative motion obeys the condition $\ell = 0$. The quantum number m also applies to the molecular hydrino electron spin flip split by electron spin-orbital coupling wherein m is a positive integer. With the substitution of Eq. (16.226) into Eq. (16.225), the unpaired-paired coupling is

$$E_{s/o} = m7.0821X10^{-7}\left(64(2)^{1.5}\alpha^5(2\pi)^2\right)m_e c^2\sqrt{\frac{3}{4}} = m7.426\ X\ 10^{-27}\ J \tag{16.227}$$

The electron paramagnetic resonance (EPR) comprises a peak at the energy equivalent position given by Eq. (16.219), that is symmetrically split into a series of pairs of peaks, one shifted downfield by the energy of Eq. (16.227), and the other shifted upfield by the energy of Eq. (16.227), wherein downfield and upfield denote lower and higher magnetic flux for a resonant transition at fixed EPR frequency, respectively.

Consider the case that the EPR frequency is 9.820295 GHz, the resonance magnetic flux B for the principal peak given by Eq. (16.219) is

$$B = \frac{h9.820295GHz}{2.0046386\mu_B} = 0.35001\ T \tag{16.228}$$

where h is Planck's constant and μ_B is the Bohr magneton. The resonance magnetic flux shift ΔB_C of a principal peak at position B_1 due to a splitting energy E_C is given by

$$\Delta B_C = B_1\frac{E_C}{h9.820295GHz} \tag{16.229}$$

Using Eqs. (16.227-16.229), the downfield and upfield shifts $\Delta B_{S/O}$ with quantized spin-orbital splitting energies $E_{S/O}$ (Eq. (16.227) and electron spin-orbital coupling quantum numbers $m = 0.5, 1, 2, 3, 5....$ are given in units of Gauss by

$$\Delta B_{S/O} = m0.35001\left[\frac{7.426\ X\ 10^{-27}\ J}{h9.820295GHz}\right]T = m3.99427\ G \tag{16.230}$$

The spin-orbital splitting shift of $m7.426\ X\ 10^{-27} J$ is independent of the applied EPR field/frequency combination for both downfield and upfield shifted peaks.

The potential energy of a superconducting quantum interference device (SQUID) given by Eq. (42.115) comprises the sum of the Josephson coupling energy of the junction and the equivalent of the magnetic energy of the loop. The free electron of $H_2(1/4)$ behaves equivalently to a superconducting quantum interference device (SQUID). In addition to the flux linked by the unpaired electron during the spin flip transition corresponding to the energy terms of the $g_{H_2(1/p)}$ (Eqs. (16.218) and (16.219)), a free electron of $H_2(1/4)$ must link the magnetic flux component corresponding to spin-orbital coupling. This flux contribution increases the magnetic energy and the energy of the combined spin flip (Eq. (16.228)) and spin-orbital coupling (Eq. (16.227)) transition energy for a given spin-orbital quantum number m. Thus, the downfield spin-orbital splitting peaks are shifted further downfield by the corresponding magnetic energies; whereas, the upfield spin-orbital splitting peaks are not shifted since the upfield peaks correspond to emission of the spin-orbital coupling transition energies alone, and the magnetic energies thermalize. The Josephson coupling energies due to fluxon linkage during spin-orbital transitions are given by Eq. (16.227), and the magnetic energies $U_{S/OMag}$ arising from the absorption of the corresponding spin-orbital coupling transitional flux are given by

$$\begin{aligned} U_{S/OMag} &= \frac{1}{2}U_0\left(\frac{2\pi(\Delta\Phi)}{\Phi_0}\right)^2 = (0.5)\frac{0.5\Delta E^{spin}_{mag\ 2.0046}}{g_{H_2(1/p)}\mu_B}\left(\frac{2\pi(\Delta B_{S/O})}{\frac{0.5\Delta E^{spin}_{mag\ 2.0046}}{g_{H_2(1/p)}\mu_B}}\right)^2 \\ &= (0.5)\frac{\left(2\pi m 0.35001\left[\frac{7.426\ X\ 10^{-27}\ J}{h9.820295GHz}\right]\right)^2}{\frac{0.5\Delta E^{spin}_{mag\ 2.0046}}{g_{H_2(1/p)}\mu_B}} = (0.5)\frac{\left(2\pi m 3.99427 X\ 10^{-4}\right)^2}{0.5\frac{h9.820295GHz}{2.0046386\mu_B}} \\ &= (0.5)\frac{\left(2\pi m 3.99427 X\ 10^{-4}\right)^2}{0.1750} X\ 10^4 G \end{aligned} \tag{16.231}$$

wherein m is the spin-orbital quantum number, ½ the spin flip transition energy corresponds to the terms U_0 and Φ_0 as given by Eqs. (16.217), (16.218), and (16.228) in units of magnetic flux (i.e. the equivalent SQUID parameters of $H_2(1/4)$ are $U_0 = \Phi_0 = \frac{0.5\Delta E^{spin}_{mag\ 2.0046}}{g_{H_2(1/p)}\mu_B}$), and the flux change due to the transition $\Delta\Phi$ is the spin-orbital splitting energy of quantum number m given in units of magnetic flux by Eqs. (16.227) and (16.230). The corresponding magnetic energies $U_{S/OMag}$ given by Eqs. (16.231), (16.217), and (16.218) in units of Joules are

$$U_{S/OMag} = g_{H_2(1/p)}\mu_B(0.5)\frac{\left(2\pi m 3.99427 X\ 10^{-4}\right)^2}{0.1750} J \tag{16.232}$$

The downfield magnetic energy shifts $U_{S/OMag}$ given by Eq. (16.232) are added to the quantized spin-orbital splitting energies $E_{S/O}$ ($\Delta B_{S/O}$) (Eq. (16.227)) to given combined quantized spin-orbital splitting energies $E_{S/Ocombined}$ in units of Joules:

$$E_{S/Ocombined} = g_{H_2(1/p)}\mu_B(0.5)\frac{\left(2\pi m 3.99427 X\ 10^{-4}\right)^2}{0.1750} J + m7.426\ X\ 10^{-27}\ J \tag{16.233}$$

The downfield magnetic energy shifts $U_{S/OMag}$ given by Eq. (16.231) are added to the quantized spin-orbital splitting energies $E_{S/O}$ (Eq. (16.230)) to given combined quantized spin-orbital downfield shift energies $\Delta B^{downfield}_{S/Ocombined}$ in units of Gauss:

$$\Delta B^{downfield}_{S/Ocombined} = -\left(m3.99427 X\ 10^{-4} + (0.5)\frac{\left(2\pi m 3.99427 X\ 10^{-4}\right)^2}{0.1750}\right) X\ 10^4 G \tag{16.234}$$

The downfield peak positions $B^{downfield}_{S/Ocombined}$ due to the combined shifts due to the magnetic energy and the spin-orbital coupling energy given by Eq. (16.228) and (16.234) are:

$$B^{downfield}_{S/Ocombined} = \left(0.35001 - m3.99427 X\ 10^{-4} - (0.5)\frac{\left(2\pi m 3.99427 X\ 10^{-4}\right)^2}{0.1750}\right) T \tag{16.235}$$

There is no magnetic energy shift for upfield shift peaks corresponding to the emission of the spin-orbital coupling energy given by Eq. (16.230). Using Eq. (16.228) and Eqs. (16.227-16.230), the upfield peak positions $B^{upfield}_{S/O}$ with quantized spin-orbital

splitting energies $E_{S/O}$ (Eq. (16.227)) and electron spin-orbital coupling quantum numbers $m = 0.5,1,2,3,5....$ are given by

$$B_{S/O}^{upfield} = 0.35001\left(1+m\left[\frac{7.426\,X\,10^{-27}\,J}{h9.820295GHz}\right]\right)T = \left(0.35001+m3.99427\,X\,10^{-4}\right)T \tag{16.236}$$

The downfield shifts due to the magnetic energies in units of Joules (Eq. (16.232)) and Gauss (Eq. (16.231)), the downfield shifts due to spin-orbital coupling energies in units of Joules (Eq. (16.227) and Gauss (Eq. (16.230)) for spin-orbital coupling quantum numbers $m = 0.5,1,2,3,5....$ are given in Table 16.48.

Table 16.48. The 9.820295 GHz $H_2(1/4)$ EPR downfield shifts due to the magnetic energies and the downfield shifts due to spin-orbital coupling energies for spin-orbital coupling quantum numbers $m = 0.5,1,2,3,5$.

m	Downfield Magnetic Energy Shift (J)	Downfield Magnetic Energy Shift (G)	Spin-Orbital Shift (J)	Spin-Orbital Shift (G)

The combined downfield shifts due to the magnetic and spin-orbital coupling energies in units of Joules (Eq. (16.233) and Gauss (Eq. (16.234)), the resulting downfield peak positions (Eq. (16.235), and the upfield peak positions (Eq. (16.236)) shifted only by the spin-orbital coupling energies (Eqs. (16.227) and (16.230)), for spin-orbital coupling quantum numbers $m = 0.5,1,2,3,5....$ wherein the principal peak with the g-factor of 2.0046386 (Eq. (16.218)) is observed at 0.35001 T (Eq. (16.228) are given in Table 16.49.

Table 16.49. The 9.820295 GHz $H_2(1/4)$ EPR combined downfield shifts due to the magnetic and spin-orbital coupling, the resulting downfield peak positions, and the upfield peak positions shifted only by the spin-orbital coupling energies for spin-orbital coupling quantum numbers $m = 0.5,1,2,3,5$.

As given in the Electron g Factor section, magnetic flux is linked by an unpaired electron in quantized units of the fluxon or the magnetic flux quantum $\frac{h}{2e}$. As shown in the Hydrino Hydride Ion Hyperfine Lines section, hydrino hydride ion $H^-(1/p)$ also possesses a linear combination of two electrons with one paired and the other unpaired in a common atomic orbital versus a MO. The emission spectrum of the binding of a free electron to a hydrino atom to form the corresponding hydrino hydride ion results in a series of evenly spaced emission peaks wherein the energy spacing matches that predicted for the binding electron to link the magnetic flux of the hydrino atom in units of the magnetic flux quantum in the bound-free emission spectral region. The flat intensity profile matches that of Josephson junctions such as ones of superconducting quantum interference devices (SQUIDs) that also link magnetic flux in quantized units of the magnetic flux quantum or fluxon $\frac{h}{2e}$. The same behavior is predicted for the linkage of magnetic flux by molecular hydrino during a spin transition and the derivation of the corresponding fluxon linkage energies follows that of Eq. (7.93) of the Hydrino Hydride Ion Hyperfine Lines section.

As given by Eq. (16.218), the fluxon links both correlated electrons such that the energy contribution of the flux linkage of a fluxon by molecular hydrino is

$$g_{H_2(1/p)} - 2 = 2\left(1+2\left(\frac{\alpha}{2\pi}+\frac{2}{3}\alpha^2\left(\frac{\alpha}{2\pi}\right)-\frac{4}{3}\left(\frac{\alpha}{2\pi}\right)^2\right)\right)-2 = 0.0046386 \tag{16.237}$$

Using the energy of MO due to an applied flux given by Eq. (16.220), wherein (i) both the magnetic moments due to spin and the corresponding induced diamagnetic moment are corrected for the vector projection of $\sqrt{\frac{3}{4}}$ (Eqs. (16.226-16.227) corresponding to an increase of the energy for resonant flux linkage, (ii) the magnetic flux density B is given by the ratio of the flux and the area, and (iii) the flux is linked in units of the fluxon $\Phi_0 = \frac{h}{2e}$, the fluxon linkage energies E_Φ by molecular hydrino $H_2(1/4)$ during a spin transition are

$$\begin{aligned} E_\Phi &= m_\Phi 4\left(\frac{\alpha}{2\pi}+\frac{2}{3}\alpha^2\left(\frac{\alpha}{2\pi}\right)-\frac{4}{3}\left(\frac{\alpha}{2\pi}\right)^2\right)\chi_{m\Phi}\frac{\mu_B}{\sqrt{s(s+1)}}B = m_\Phi 0.0046386\frac{\chi_{m\Phi}\mu_B}{\sqrt{s(s+1)}}\left(\frac{j\Phi_0}{A}\right) \\ &= m_\Phi\left(j0.0046386\frac{\chi_{m\Phi}\mu_B}{\sqrt{s(s+1)}}\frac{\mu_0}{r^3}\left(\frac{e\hbar}{2m_e}\right)\right) \end{aligned} \tag{16.238}$$

In Eq. (16.238), the energy of flux linkage is an integer function of the components of angular moment involved in the splitting of the principal transition corresponding to the electron fluxon quantum number m_Φ. Therefore, the electron fluxon quantum number m_Φ has the following integer values: (i) the electron fluxon quantum number m_Φ corresponding to the spin-orbital coupling involving the intrinsic spin of $\frac{\hbar}{2}$ is $m_\Phi = 1$, (ii) the electron fluxon quantum number m_Φ corresponding to the spin with $m = 1$ involving the semimajor axis spin is $m_\Phi = 2$, and (iii) the electron fluxon quantum number m_Φ corresponding to the spin with $m > 1$; $|\Delta m| = 1$ involving the semimajor axis spin and relative motion of the two electrons of the $H_2(1/4)$ MO is $m_\Phi = 3$. In addition, j is an integer corresponding to the number of fluxons linked having fluxion linkage quantum number m_Φ, $s = 1/2$, A is the area of the continuous distribution of current element loops (Force Balance of Hydrogen-Type Molecules section and Figure 11.2) linked by the integer number of fluxons as given in the Electron g Factor section, and the magnitude of the diamagnetic susceptibility $\chi_{m\Phi}$ is given by

$$\chi_{m\Phi} = \alpha\left(p28.01 + p^2 1.49\ X\ 10^{-3}\right) ppm = 8.1777\ X\ 10^{-7} \tag{16.239}$$

With the substitution of Eq. (16.239) into Eq. (16.238), E_Φ is

$$E_\Phi = m_\Phi\left(j(0.0046386)\frac{\mu_0\left(8.1777\ X\ 10^{-7}\right)\mu_B^2}{\sqrt{\frac{3}{4}}\left(\frac{a_0}{4\sqrt{2}}\right)^3}\right) = m_\Phi\left(j5.7830\ X\ 10^{-28}\ J\right) \tag{16.240}$$

wherein the semiminor radius of the $H_2(1/4)$ MO is given by Eq. (11.205) with $p = 4$. Using Eq. (16.229) with the E_Φ, the fluxon linkage energy of $H_2(1/4)$ (Eq. (16.240)), and the spin-orbital peak positions (Eqs. (16.235) and (16.236)), the separation ΔB_Φ of the integer series of peaks at each spin-orbital peak position (Table 16.49) for an EPR frequency of 9.820295 GHz is given by

$$\Delta B_\Phi^{downfield} = \left(0.35001 - m3.99427X\ 10^{-4} - (0.5)\frac{\left(2\pi m3.99427X\ 10^{-4}\right)^2}{0.1750}\right)\left[\frac{m_\Phi 5.7830\ X\ 10^{-28}\ J}{h9.820295GHz}\right]X\ 10^4 G \tag{16.241}$$

and

$$\Delta B_\Phi^{upfield} = \left(0.35001 + m3.99427X\ 10^{-4}\right)\left[\frac{m_\Phi 5.7830\ X\ 10^{-28}\ J}{h9.820295GHz}\right]X\ 10^4 G \tag{16.242}$$

The 9.820295 GHz $H_2(1/4)$ EPR spectral separations ΔB_Φ (Eqs. (16.235) and (16.236)) of each integer series of the peaks comprising sub-splitting of the downfield and upfield peaks of Table 16.49 corresponding to the principal peak having a g-factor of 2.0046386 (Eq. (16.218)) split by quantized spin-orbital coupling energies $E_{S/O}$ (Eqs. (16.227) and (16.230)) and magnetic energies $U_{S/OMag}$ (Eqs. (16.231) and (16.232)) for electron spin-orbital coupling quantum numbers $m = 0.5, 1, 2, 3, 4, 5$ and electron fluxon quantum numbers $m_\Phi = 1, 2, 3$ (Eq. (16.240) are given in Table 16.50.

Table 16.50. The 9.820295 GHz $H_2(1/4)$ EPR spectral separation ΔB_Φ of each integer series of the peaks comprising sub-splitting of the downfield and upfield peaks of Table 16.49 for electron spin-orbital coupling quantum numbers $m = 0.5,1,2,3,4,5$ and electron fluxon quantum numbers $m_\Phi = 1,2,3$.

m	m_Φ	Downfield Peak Position (T)	ΔB_Φ (G)	Upfield Peak Position (T)	ΔB_Φ (G)
0.5	1	0.34980	0.3109	0.35021	0.3112
1	2	0.34959	0.6214	0.35041	0.6228
2	3	0.34914	0.9309	0.35081	0.9353
3	3	0.34865	0.9296	0.35121	0.9364
4	3	0.34812	0.9282	0.35160	0.9375
5	3	0.34756	0.9267	0.35200	0.9385

The spin-orbital splitting peak intensity for electron spin-orbital coupling quantum number $m = 0.5$ is predicted to be dominant due to the high cross section of the spin flip transition to involve a torque about the intrinsic angular moment vector as shown in Resonant Precession of the Spin-1/2-Current-Density Function Gives Rise to the Bohr Magneton section. For integer electron spin-orbital coupling quantum number m spin-orbital splitting peaks, the relative intensities are predicted to decrease with integer electron spin-orbital coupling quantum number m. In the case that the statistical population obeys the rules of multipole transitions, the relative peak intensities according to Eqs. (1.7-1.8) and Eq. (1.19) go as

$$\frac{I_{m+1}}{I_m} = \frac{m(m+1)}{(m+1)(m+2)} = \frac{m}{(m+2)}; m = 2,3,4.. \tag{16.243}$$

Furthermore, consider the relative intensities of fluxon peaks within an integer series. If the cross-sectional area of the flux linker is constant relative to the flux source, then the line intensities for the sub-splitting would be equal. However, the cross-sectional area of the electron current relative to the applied field changes as the current comprising a continuous ensemble of current loops flips orientation by 180°. The current flowing over the surface of the prolate spheroidal to reverse the spin direction by 180° is a mechanism whereby the relative intensities of the sub-splitting is higher for the center lines compared to those at the extrema. The line intensities and widths reflect the electron MO geometrical form factor in the case of $m = 0.5$.

In summary, the predicted $H_2(1/4)$ EPR spectrum comprises a principal peak with a theoretical g-factor of 2.0046386 (Eq. (16.218)) that is split by spin-orbital coupling energies $E_{S/O}$ and corresponding magnetic energies $U_{S/OMag}$ on the downfield side into a series of pairs of peaks with members separated by the sum of $E_{S/O}$ (Eqs. (16.227) and (16.230)) and $U_{S/OMag}$ (Eqs. (16.231) and (16.232)) that is a function of electron spin-orbital coupling quantum number m. Each spin-orbital splitting peak is further sub-split into a series of equally spaced peaks of integer fluxon energy ΔB_Φ (Eqs. (16.241) and (16.242)) that is a function of electron fluxon quantum number m_Φ. As given in the Hydrino Hydride Ion Hyperfine Lines section, the pattern of integer-spaced peaks predicted for the EPR spectrum of $H_2(1/4)$ is very similar to that experimentally observed on the hydrino hydride ion that also comprises a paired and unpaired electron in a common orbital, except that the orbital is an atomic orbital [132-135]. The peak separations and sub-splitting due to spin-orbital splitting energies, spin-orbital splitting magnetic energies, and fluxon energies may deviate from the values given in Tables 16.49 and 16.50. Interactions may exist with the matrix surrounding the hydrino molecule. For example, protons of water molecules absorbed as waters of hydration of a crystalline matrix having trapped hydrino molecules could cause and external nuclear splitting effect.

The predicted EPR spectrum was confirmed experimentally [131]. The 9.820295 GHz EPR spectrum was performed on a white polymeric compound (WPC) identified by X-ray diffraction (XRD), energy-dispersive X-ray spectroscopy (EDS), transmission electron spectroscopy (TEM), scanning electron microscopy (SEM), time-of-flight secondary ionization mass spectroscopy (ToF-SIMs), Rutherford backscattering spectroscopy (RBS), and X-ray photoelectron spectroscopy (XPS) as GaOOH:H_2(1/4). The WPC was formed by dissolving Ga_2O_3 collected from a hydrino reaction run in a SunCell® in 4M aqueous KOH, allowing fibers to grow, and float to the surface where they were collected by filtration. The white fibers were not solution in concentrated acid or base; whereas control GaOOH is. No white fibers formed in control solutions. Control GaOOH showed no EPR spectrum. The experimental EPR was acquired by Professor Fred Hagen, TU Delft, with a high sensitivity resonator at a microwave power of -28 dB and a modulation amplitude of 0.02 G, that can be changed to 0.1 G since Dr. Hagen rigorously determined that the minimum line width is 0.15 to 0.2 G. The average error between the EPR spectrum and theory for peak positions given in Tables 16.49-16.50 was 0.097 G. The EPR spectrum was replicated by Bruker using two instruments on two samples.

Specifically, the observed principal peak at g = 2.0045(5)) was assigned to the theoretical peak having a g-factor of 2.0046386 (Eq. (16.218)). This principal peak was split into a series of pairs of peaks with members separated by energies

matching $E_{S/O}$ (Eqs. (16.227) and (16.230)) corresponding to each electron spin-orbital coupling quantum number m. The results confirmed the spin-orbital coupling between the spin magnetic moment of the unpaired electron and an orbital diamagnetic moment induced in the paired electron alone or in combination with rotational current motion about the semimajor molecular axis that shifted the flip energy of the spin magnetic moment. The data further matched the theoretically predicted one-sided tilt of the spin-orbital splitting energies wherein the downfield shift was observed to increase with quantum number m due to the magnetic energies $U_{S/OMag}$ (Eqs. (16.231) and (16.232)) of the corresponding magnetic flux linked during a spin-orbital transition. Each spin-orbital splitting peak was further sub-split into a series of equally spaced peaks that matched the integer fluxon energies ΔB_Φ (Eqs. (16.241) and (16.242)) dependent on electron fluxon quantum number m_Φ corresponding to the number of angular momentum components involved in the transition. The evenly spaced series of sub-splitting peaks was assigned to flux linkage during the coupling between the paired and unpaired magnetic moments in units of the magnetic flux quantum $\frac{h}{2e}$ while a spin flip transition occurs. The EPR spectrum recorded at different frequencies showed that the peak assigned the g factor of 2.0046386 (Eq. (16.218)) remained at constant g factor. Moreover, the peaks, shifted by the fixed spin-orbital splitting energies relative to this true g-factor peak, exactly maintained the separation of the spin-orbital splitting energies independent of frequency as predicted.

Another consideration is that molecular hydrino can also form dimers that would alter the EPR spectrum. Consider the splitting energy of interaction with two axially aligned magnetic moments of a $H_2(1/4)$ dimer. With the substitution of a Bohr magneton μ_B for each axially aligned magnetic moment and the $H_2(1/4)$ dimer separation given by Eq. (16.202) for $|\mathbf{r}|$ into Eq. (16.223), the energy $E_{mag\ [H_2(1/4)]_2\ e\text{-}dipole}$ to flip the spin direction of two electron magnetic moments of $\left[H_2(1/4)\right]_2$ is

$$\begin{aligned} E_{mag\ [H_2(1/4)]_2\ e\text{-}dipole} &= -\frac{2\mu_0\mu_B^2}{4\pi r^3} \\ &= -\frac{\mu_0\left(9.27400949X10^{-24}JT^{-1}\right)^2}{2\pi\left(1.028X10^{-10}m\right)^3} \\ &= -1.584X10^{-23}\ J = -9.885X10^{-5}\ eV = 23.90\ GHz = 0.7972\ cm^{-1} \end{aligned} \tag{16.244}$$

ROTATIONAL ENERGIES DUE TO THE SPIN MAGNETIC MOMENT OF $H_2(1/4)$

Molecular hydrino $H_2(1/p)$ possesses an unpaired electron that causes rotational transitions to be forbidden. This selection rule barrier to observing infrared and Raman spectra may be circumvented by application of an external magnetic field or by recording the spectrum on a compound or material with intrinsic magnetization such as one being ferromagnetic or paramagnetic. An example of the former is molecular hydrino bonded or absorbed on the surface of a nickel or iron foil. An example of the latter is a paramagnetic compound that cages the molecular hydrino such as FeOOH, Fe_2O_3 or a compound that may be diamagnetic but possess paramagnetic ions in proximity to $H_2(1/p)$ such as Ga^{3+} ions in the case of $GaOOH$ that serves as a cage for $H_2(1/p)$.

The presence of molecular hydrino in strong matrix magnetic field may result in the alignment of the free electron angular moment of $\frac{\hbar}{2}$ along the magnetic field vector direction in either the z-axis or the y-axis direction of the coordinates of $H_2(1/p)$ shown in Figure 11.4. The alignment permits the excitation of a concerted transition of a rotational molecular hydrino transition coupling to the spin-orbital splitting and fluxon linkage sub-splitting of the free electron energy levels. The spin flip energy given by Eq. (16.219) with an exemplary intrinsic field of 1 T is

$$\Delta E_{mag\ 2.0046}^{spin} = g_{H_2(1/p)}\mu_B B = 2.0046386\mu_B B = 1.85910\ X\ 10^{-23} J\ (0.93588\ cm^{-1}) \tag{16.245}$$

To conserve the photon's angular momentum of $\hbar$, rotational excitation requires $\hbar$ of angular momentum along the axis of molecular rotation, a semiminor axis being either the z-axis or y-axis. The $\hbar$ of angular momentum gives rise to a corresponding magnet moment of a Bohr magneton along this rotational angular momentum axis. Typically, the unpaired electron of $H_2(1/p)$ gives rise to a Bohr magneton of magnetic moment along the internuclear axis when a magnetic field is applied. However, the molecular rotation of the hydrino molecule about one of the semiminor axes causes the excitation of the semimajor-axis Bohr magneton of magnetic moment to be forbidden. The rotational transition energy may be split by the spin-orbital energy given by Eq. (16.225), except that the orbital component of spin-orbital splitting is not diamagnetically induced such that $\chi_m = 1$ and the spin-orbital energy $E_{S/O,rot}$ due to rotational excitation is:

$$E_{S/O,rot} = m\left[\frac{1}{\left(4\sqrt{2}\right)^{-3}}\alpha^5\left(2\pi\right)^2 m_e c^2\sqrt{\frac{3}{4}}\right] \tag{16.246}$$
$$= m1.04853X\ 10^{-20}\ J \quad (m6.54434X\ 10^{-2}eV,\ m527.83\ cm^{-1})$$

wherein $m = 0.5,1,2,3,\ldots$. The spin-orbital splitting energies due to rotation are given in Table 16.51.

The energies of the concerted excitation of the rotational and spin-orbital coupling transitions are sub-split by the energy corresponding to flux linkage in units of the magnetic flux quantum $\frac{h}{2e}$. The free electron angular momentum of $\frac{\hbar}{2}$ and the rotational angular momentum of $\hbar$ add when the corresponding vectors are aligned along a common z-axis to give a resultant angular momentum of $L=\frac{3}{2}\hbar$. The energy contribution of the flux linkage of a fluxon by molecular hydrino is given by Eq. (16.238) with $\chi_{m\Phi}=1$ since the orbital component of spin-orbital coupling is not diamagnetically induced. In the case of $L=\frac{3}{2}\hbar$, the $H_2\left(1/4\right)$ fluxon linkage energies $E_{\Phi,rot,concerted}$ for fluxon sub-splitting quantum numbers $m_{\Phi 3/2}=0.5,1,2,3...$ due to spin-orbital coupling to a molecular rotational transition are

$$E_{\Phi,rot,concerted} = m_{\Phi 3/2}4\left(\frac{\alpha}{2\pi}+\frac{2}{3}\alpha^2\left(\frac{\alpha}{2\pi}\right)-\frac{4}{3}\left(\frac{\alpha}{2\pi}\right)^2\right)\frac{3}{2}\mu_B B$$
$$= m_{\Phi 3/2}j\frac{3}{2}\left(j0.0046386\frac{\mu_0\mu_B}{r^3}\left(\frac{e\hbar}{2m_e}\right)\right) \tag{16.247}$$
$$= m_{\Phi 3/2}46.24\ cm^{-1}$$

wherein j is an integer corresponding to the number of fluxons linked having fluxon linkage quantum number $m_{\Phi 3/2}$ and the semiminor radius of the $H_2\left(1/4\right)$ MO is given by Eq. (11.205) with $p=4$ ($r=\frac{a_0}{4\sqrt{2}}$). As in the case with spin flip transitions observable by EPR spectroscopy, the fluxon sub-splitting quantum number is determined by the number of angular momentum components active during the transition. Due to the nature of the rotation transition wherein the rotational quantum number J may be arbitrarily large, the upper range of the fluxon sub-splitting quantum number is not bounded.

Alternatively, the spin component of $\frac{\hbar}{2}$ may align perpendicular to the rotational angular momentum of $\hbar$ to give a resultant z-axis angular momentum of $L=\hbar$ wherein the spin component averages to zero since it rotates about the z-axis due to molecular rotation. In the case of $L=\hbar$, the $H_2\left(1/4\right)$ fluxon linkage energies $E_{\Phi,rot}$ for fluxon sub-splitting quantum numbers $m_\Phi=0.5,1,2,3,...$ due to spin-orbital coupling to a molecular rotational transition are

$$E_{\Phi,rot} = m_\Phi\left(j0.0046386\frac{\mu_B^2\mu_0}{r^3}\right) \tag{16.248}$$
$$= m_\Phi j30.83\ cm^{-1}$$

wherein j is an integer corresponding to the number of fluxons linked having fluxon linkage quantum number m_Φ and the semiminor radius of the $H_2\left(1/4\right)$ MO is given by Eq. (11.205) with $p=4$ ($r=\frac{a_0}{4\sqrt{2}}$). The fluxon linkage energies $E_{\Phi,rot}$ due to spin-orbital coupling to molecular rotation transition are given in Table 16.51.

The absorption of fluxons increases the magnetic energy of $H_2\left(1/p\right)$. Using Eq. (16.231), the Josephson coupling energies due to fluxon linkage during concerted rotational-spin rotational and spin-orbital transitions are given by Eq. (16.247), and the magnetic energies $U_{S/OMag,concerted}$ arising from the absorption of the integer number of fluxons j having fluxon linkage quantum number $m_{\Phi 3/2}$ are given by

$$U_{S/OMag,concerted} = \frac{1}{2}U_0\left(\frac{2\pi\left(\Delta\Phi\right)}{\Phi_0}\right)^2$$
$$= 46.24\ cm^{-1}\left(0.5\right)\left(\frac{jm_{\Phi 3/2}46.24\ cm^{-1}}{1950\ cm^{-1}}\right)^2 \tag{16.249}$$
$$= m_{\Phi 3/2}^2 0.0130 j^2\ cm^{-1}$$

wherein $U_0 = 46.24\ cm^{-1}; \Delta\Phi = E_{\Phi,rot,concerted} = m_{\Phi 3/2} 46.24\ cm^{-1}$ (Eq. (16.247)), and the energy between rotational transitions corresponds to the term Φ_0 (Eq. (16.256, $p = 4$)). The fluxon peak spacing increases as the energy of the concerted rotation-fluxon absorption transition increases and decreases in the case of emission.

Using Eq. (16.231), the magnetic energies $U_{S/OMag}$ arising from the absorption of the integer number of fluxons j having fluxon linkage quantum number m_Φ during concerted rotational and spin-orbital transitions are given by

$$\begin{aligned} U_{S/OMag} &= \frac{1}{2} U_0 \left(\frac{2\pi(\Delta\Phi)}{\Phi_0} \right)^2 \\ &= 30.83\ cm^{-1} (0.5) \left(\frac{j m_{\Phi 3/2} 30.83\ cm^{-1}}{1950\ cm^{-1}} \right)^2 \\ &= m_{\Phi 3/2}^2 0.00385 j^2\ cm^{-1} \end{aligned} \tag{16.250}$$

wherein $U_0 = 30.83\ cm^{-1}; \Delta\Phi = E_{\Phi,rot} = m_{\Phi 3/2} 30.83\ cm^{-1}$ (Eq. (16.248)), and the energy between rotational transitions corresponds to the term Φ_0 (Eq. (16.256, $p = 4$)). The fluxon peak spacing increases as the energy of the concerted rotation-fluxon absorption transition increases and decreases in the case of emission.

Table 16.51. . The electron spin-orbital coupling splitting energies and fluxon sub-splitting energies of molecular rotational transitions for spin-orbital coupling quantum numbers $m = 0.5,1,2,3,...,10$ and for electron fluxon quantum numbers $m_\Phi = 1,2,3,...,10$ and $m_{\Phi 3/2} = 1,2,3,...,10$.

m	Spin-Orbital Splitting Energy (cm^{-1})	m_Φ	Fluxon Sub-Splitting Energy (cm^{-1})	$m_{\Phi 3/2}$	Fluxon Sub-Splitting Energy (cm^{-1})
0.5	264	0.5	15.4	0.5	23.1
1	528	1	30.8	1	46.2

The observation of spin-orbital transitions by Raman spectroscopy may be greatly enhanced by the deposition of molecular hydrinos on a metal surface to enhance the Raman spectrum. Surface enhanced Raman (SER) is very sensitive because of the surface plasmon waves set up by the stimulating wavelength. The surface plasmon field may extend about 40-60 nm below the surface, providing some depth sensitivity in the material.

The moment of inertia may be measured using rotational energy spectroscopy such as Raman spectroscopy, and using the known nuclear masses, the moment of inertia gives the nuclear separation which is characteristic of and identifies molecular hydrino of a given quantum state p. Specifically, for a diatomic molecule having atoms of masses m_1 and m_2, the moment of inertia is (Eq. (12.66)):

$$I = \mu r^2 \tag{16.251}$$

where μ is the reduced mass given by (Eq. (12.67)):

$$\mu = \frac{m_1 m_2}{m_1 + m_2} \tag{16.252}$$

and where r is the distance between the centers of the atoms, the internuclear distance. The rotational energy levels follow from Eq. (1.71) and are given by (Eq. (12.68)):

$$E_{rotational} = \frac{\hbar^2}{2I} J(J+1) \tag{16.253}$$

where J is an integer. The pure rotational energies of hydrogen type molecules for transition from the J to the quantized J'

rotational state are given by (Eq. (12.77)):

$$\begin{aligned}\Delta E_{J\to J'} &= E_{J'} - E_J \\ &= \frac{p^2\hbar^2}{2\left(0.5m_p\left(7.411X10^{-11}m\right)^2\right)}\left(J'\left(J'+1\right)-J\left(J+1\right)\right) \\ &= \frac{\left(J'\left(J'+1\right)-J\left(J+1\right)\right)}{2}p^2 121.89\ cm^{-1}\end{aligned} \tag{16.254}$$

wherein m_p is the mass of the proton, the moment of inertia $I = 0.5m_p\left(\frac{7.411X10^{-11}m}{p}\right)^2$, and the integer-squared dependence is due to the reciprocal integer dependence of the internuclear distance given by (Eq. (12.76)):

$$2c' = \frac{0.7411}{p}\ \text{Å} \tag{16.255}$$

For example, the predicted rotational energy of $H_2\left(1/4\right)$ is four squared or 16 times that of H_2 due to the internuclear distance being one fourth that of H_2 (Eq. (16.254)). At ambient laboratory temperature, molecules overwhelmingly populate the rotational state $J = 0$. Then, Eq. (16.253) becomes

$$\Delta E_{J=0\to J'} = \frac{J'\left(J'+1\right)}{2}p^2 121.89\ cm^{-1} \tag{16.256}$$

Molecular hydrino $H_2\left(1/p\right)$ is a diatomic molecule comprising two protons and two electrons, except that it is unique from molecular hydrogen in that it has an unpaired electron having an intrinsic angular momentum of $\frac{\hbar}{2}$. This electron spin angular momentum may align along the same axis as the rotational angular of $\hbar$ or transverse to it. Consider that the rotational energy $E_{rotational}$ of $H_2\left(1/p\right)$ about z-axis which is the common axis of the intrinsic electron angular momentum of $\frac{\hbar}{2}$ and rotational angular momentum of $\hbar$. The rotational energy due to the concerted double excitation of rotation due to spin and diatomic rotation is given by the sum of the diatomic molecular rotational energy given by Eq. (16.253) and the spin rotational energy also given by Eq. (16.253) with the exception that the rotational quantum number J can only change by ± 1:

$$\begin{aligned}E_{rotational+spin} &= \frac{\hbar^2}{2I}\left(J'\left(J'+1\right)-J\left(J+1\right)\right)+\frac{\hbar^2}{I}\left(J+1\right) \\ &= \left(\frac{J'^2+J'-J^2+J+2}{2}\right)p^2 121.89\ cm^{-1}\end{aligned} \tag{16.257}$$

In the case that the initial rotational state is $J = 0$, Eq. (16.256) becomes

$$\begin{aligned}E_{rotational+spin} &= \frac{\hbar^2}{2I}\left(J'\left(J'+1\right)-J\left(J+1\right)\right)+\frac{\hbar^2}{I}\left(J+1\right) \\ &= \left(\frac{J'^2+J'+2}{2}\right)p^2 121.89\ cm^{-1}\end{aligned} \tag{16.258}$$

Consider that the diatomic molecular rotation is about the z-axis such that the corresponding rotational angular momentum of $\hbar$ is aligned along the z-axis. In the case that the axis of the intrinsic electron spin angular momentum of $\frac{\hbar}{2}$ is along the orthogonal semiminor axis, the y-axis, the rotation energy $E_{rotational}$ of $H_2\left(1/p\right)$ is given by Eq. (16.255).

The radiation of a multipole of order (ℓ, m_ℓ) carries $m\hbar$ units of the z component of angular momentum per photon of energy $\hbar\omega$. Thus, the z component of the angular momentum of the corresponding excited rotational state is (Eq. (12.69)):

$$L_z = m\hbar \tag{16.259}$$

Thus, the selection rule for dipole and quadrupole rotational transitions are (Eq. (12.70)):

$$\Delta J = \pm 1 \tag{16.260}$$

and

$$\Delta J = \pm 2 \tag{12.261}$$

Not only are the lowest energy Raman transitions for pure rotational transitions (Eq.(16.255)) and for concerted rotational-spin transition (Eq. (16.257)) allowed by each of the selection rules given by Eqs. (16.259) and (16.260), but coupling of allowed dipole and quadrupole transitions permit excitation of higher rotational energy levels. Isotopic substitution and ortho-para state occupancy also determines the section rules of Raman transitions. Exemplary transitions are given in Table 16.52.

Due to the equivalence of the two semiminor axes, a double rotational excitation comprising the superposition of the independent rotations about each may occur. The energy of the double excitation of these two rotational modes is the sum of the individual pure and concerted rotational transitions. Using Eqs. (16.256) and (16.258), the energies $E_{double\ rotation}$ of the combined rotational excitations are

$$E_{double\ rotational} = \left(\frac{J_c'^2 + J_c'^2 + 2}{2} \right) + \frac{J_p' \left(J_p' + 1 \right)}{2} p^2 121.89\ cm^{-1} \tag{16.262}$$

Exemplary transitions are given in Table 16.52.

Table 16.52. H_2(1/4) Raman energies for (i) pure $J = 0$ to $J' = 1,2,3,...$ rotational transitions, (ii) concerted $J = 0$ to $J' = 0,1,2,3,...$ molecular rotational transition involving a spin rotation transition having the spin rotational state quantum number change from $J = 0$ to $J = 1$, and double transition having energies given by the sum of the independent transitions.

J'	Pure Rotational Transition (cm^{-1})	Concerted Molecular Rotational-Spin Rotation Transition (cm^{-1})	J_p' / J_c'	Double Rotational Transition (cm^{-1})
0	0	1950	1/0	3900
1	1950	3900	2/0	7801
2	5851	7801	2/1	9751
3	11701	13652	3/0	13652
4	19502	21453	3/1	15602
5	29254	31204	3/2	19502
6	40955	42905	4/0	21453
7	54607	56557	4/1	23403
8	70209	72159	4/2	27303
9	87761	89711	4/3	33154
10	107263	109213	5/0	31204

The rotation energies shown in Table 16.52 with spin-orbital splitting and fluxon linkage sub-splitting energy shifts were observed by Raman spectroscopy [136]. Moreover, some of the observed lines matched those of the Diffuse Interstellar Bands (DIBs) [136, 137].

END-OVER-END ROTATION OF HYDROGEN-TYPE MOLECULAR DIMERS

The reduced masses of hydrogen-type molecular dimers having two protons μ_{H_2} or deuterons μ_{D_2} are given by Eqs. (12.67) and (12.72) where $m_1 = m_2 = m_p$ and $m_1 = m_2 = 2m_p$, respectively:

$$\mu_{H_2} = \frac{m_p m_p}{m_p + m_p} = \frac{1}{2} m_p \tag{16.263}$$

$$\mu_{D_2} = \frac{2m_p 2m_p}{2m_p + 2m_p} = m_p \tag{16.264}$$

where m_p is the mass of the proton. The moment of inertia of hydrogen-type molecular dimers is given by summation of the moments of inertial for two sets of nuclei, each equidistant from the center of rotation along the x-axis. The moment of inertia of the nearest neighbor nuclei is given by substitution of the reduced mass (Eqs. (16.263) or (16.264)) for μ of Eq. (12.66) and substitution of the internuclear distance $2c'_{dimer}$ (Eq. (16.181) or (16.202))for r of Eq. (12.66). The moment of inertia of the farthest neighbor nuclei is given by substitution of the reduced mass (Eqs. (16.263) or (16.264)) for μ of Eq. (12.66) and substitution of the internuclear distance $2c'_{dimer}$ (Eq. (16.181) or (16.202))) plus the internuclear distance $2c'$ (Eq. (11.204) for r of Eq. (12.66).

$$I\left([H_2]_2\right)=\frac{m_p}{2}\left[\left(7.61404a_0\right)^2+\left(7.61404a_0+\sqrt{2}a_0\right)^2\right] \tag{16.265}$$

$$I\left([D_2]_2\right)=m_p\left[\left(7.61404a_0\right)^2+\left(7.61404a_0+\sqrt{2}a_0\right)^2\right] \tag{16.266}$$

$$I\left([H_2(1/4)]_2\right)=\frac{m_p}{2}\left[\left(1.94251a_0\right)^2+\left(1.94251a_0+\frac{\sqrt{2}}{4}a_0\right)^2\right] \tag{16.267}$$

$$I\left([H_2(1/4)]_2\right)=m_p\left[\left(1.94251a_0\right)^2+\left(1.94251a_0+\frac{\sqrt{2}}{4}a_0\right)^2\right] \tag{16.268}$$

Using Eqs. (12.71), (12.67), and (12.74), the rotational energies absorbed by a hydrogen-type molecular dimer with the transition from the state with the rotational quantum number J to one with the rotational quantum number $J+1$ are:

$$\begin{aligned}\Delta E\left([H_2]_2\right)&=E_{J+1}-E_J\\&=\frac{\hbar^2}{I\left([H_2]_2\right)}\left[J+1\right]\\&=\frac{\hbar^2}{\frac{m_p}{2}\left[\left(7.61404a_0\right)^2+\left(7.61404a_0+\sqrt{2}a_0\right)^2\right]}\\&=\left[J+1\right]1.71\ cm^{-1}\end{aligned} \tag{16.269}$$

$$\begin{aligned}\Delta E\left([D_2]_2\right)&=E_{J+1}-E_J\\&=\frac{\hbar^2}{I\left([D_2]_2\right)}\left[J+1\right]\\&=\frac{\hbar^2}{m_p\left[\left(7.61404a_0\right)^2+\left(7.61404a_0+\sqrt{2}a_0\right)^2\right]}\\&=\left[J+1\right]0.86\ cm^{-1}\end{aligned} \tag{16.270}$$

$$\begin{aligned}\Delta E\left([H_2(1/4)]_2\right)&=E_{J+1}-E_J\\&=\frac{\hbar^2}{I\left([H_2(1/4)]_2\right)}\left[J+1\right]\\&=\frac{\hbar^2}{\frac{m_p}{2}\left[\left(1.94251a_0\right)^2+\left(1.94251a_0+\frac{\sqrt{2}}{4}a_0\right)^2\right]}\\&=\left[J+1\right]44.30\ cm^{-1}\end{aligned} \tag{16.271}$$

$$\begin{aligned}\Delta E\left([D_2(1/4)]_2\right)&=E_{J+1}-E_J\\&=\frac{\hbar^2}{I\left([D_2(1/4)]_2\right)}\left[J+1\right]\\&\frac{\hbar^2}{m_p\left[\left(1.94251a_0\right)^2+\left(1.94251a_0+\frac{\sqrt{2}}{4}a_0\right)^2\right]}\\&=\left[J+1\right]22.15\ cm^{-1}\end{aligned} \tag{16.272}$$

The results for H_2 and D_2 dimers (Eqs. (16.269) and (16.270)) match experimental observations [138].

REACTION KINETICS AND THERMODYNAMICS

Reaction kinetics may be modeled using the classical solutions of reacting species and their interactions during collisions wherein the bond order of the initial and final bonds undergo a decreasing and increasing bond order, respectively, with conservation of charge and energy. Collisions can be modeled starting with the simple hard sphere model with conservation of energy and momentum. The energy distribution may be modeled using the appropriate statistical thermodynamics model such as

Maxwell-Boltzmann statistics. Low-energy collisions are elastic, but for sufficiently high energy, a reaction may occur. Hot reacting species such as molecules at the extreme of the kinetic energy distribution can achieve the transition state, the intermediate species at the cross over point in time and energy between the reactants and products. The rate function to form the transition state may depend on the collisional orientation as well as the collisional energy. Bond distortion conserves the energy and momentum of the collision from the trajectories of the reactants. For sufficient distortion due to a sufficiently energetic collision at an appropriate relative orientation, a reaction occurs wherein the products exiting the collision event are different from the reactants entering the collision. The initial reactant energy and momentum as well as those arising from any bonding energy changes are conserved in the translational, rotational, and vibrational energies of the products. The bond energy changes are given by the differences in the energies of the product and reactants molecules wherein the geometrical parameters, energies, and properties of the latter can be solved using the same equations as those used to solve the geometrical parameters and component energies of the individual molecules as given in the Organic Molecular Functional Groups and Molecules section. The bond energy changes at equilibrium determine the extent of a reaction according to the Gibbs free energy of reaction. Whereas, the corresponding dynamic reaction-trajectory parameters of translational, rotational, and vibrational energies as well as the time dependent electronic energy components such as the electron potential and kinetic energies of intermediates correspond to the reaction kinetics. Each aspect will be treated next in turn.

Consider the gas-phase reaction of two species A and B comprising the reactants that form one or more products C_n where n is an integer:

$$A+B \rightleftarrows C_1+\cdots+C_n \tag{16.273}$$

Arising from collisional probabilities, the concentrations (denoted $[A],[B],...$) as a function of time can be fitted to a second-order rate law

$$-\frac{d[A]}{dt}=k[A][B]-k'\prod_{i=1}^{n}[C_i] \tag{16.274}$$

where k and k' are the forward and reverse rate constants. The equilibrium constant K corresponding to the balance between the forward and reverse reactions is given by the quotient of the forward and reverse rate constants:

$$K=\frac{k}{k'} \tag{16.275}$$

The relationship between the temperature-dependent equilibrium constant and the standard Gibbs free energy of reaction $\Delta G_T^0(T)$ at temperature T is**:**

$$K=Q_K(T)e^{\frac{-\Delta G_T^0(T)}{RT}} \tag{16.276}$$

where R is the ideal gas constant,

$$Q_K(T)=\frac{\prod_{i=1}^{n}[C_i]}{[A][B]} \tag{16.277}$$

is the reaction quotient at the standard state, and

$$\Delta G_T^0(T)=\Delta H_T^0(T)-T\Delta S_T^0 \tag{16.278}$$

where $\Delta H_T^0(T)$ and ΔS_T^0 are the standard-state enthalpy and entropy of reaction, respectively. Rearranging Eq. (16.276) gives the free energy change upon reaction:

$$\Delta G=RTln\frac{Q_K}{K} \tag{16.279}$$

If the instantaneous free energy change is zero, then the reaction is at equilibrium. An exergonic or work-producing reaction corresponds to the cases with $\Delta G_T^0(T)$ or ΔG negative, and endergonic or work consuming reactions corresponds to positive values. The enthalpy of reaction or heat of reaction at constant pressure is negative for an exothermic (heat releasing) reaction, and is positive for an endothermic (heat absorbing) reaction. The enthalpy of reaction may be calculated by Hess's law as the difference of the sum of the heats of formation of the products minus the sum of the heats of formation of the reactants wherein the individual heats of the molecules are solved using the equations given in the Organic Molecular Functional Groups and Molecules section.

TRANSITION STATE THEORY

Transition state theory (TST) has been widely validated experimentally. It entails the application of classical trajectory calculations that allow the study of the dynamics at the microscopic level such as differential cross sections, total cross sections, and product energy distributions, as well as at the macroscopic level for the determination of thermal rate constants by solving the classical equations of motion with the formation of the transition state. The reaction trajectory parameters give rise to terms of a classical thermodynamic kinetics equation discovered in 1889 by Arrhenius and named after him. The data of the variation of the rate constant k with temperature of many reactions fit the Arrhenius equation given by

$$k = Ae^{\frac{-E_a}{RT}} \tag{16.280}$$

where E_a is the activation energy and A is a preexponential or frequency factor that may have a relatively small temperature dependence compared to the exponential term of Eq. (16.244). For reactions that obey the Arrhenius equation, when $\ln k$ is plotted versus $1/T$ in a so-called Arrhenius plot, the slope is the constant $-E_a/R$, and the intercept is A. Eq. (16.280) confirms that typically two colliding molecules require a certain minimum kinetic energy of relative motion to sufficiently distort initial reactant bonds and concomitantly allow nascent bonds to form. The crossover species from reactants to products called the transition state will proceed through the minimum energy complex involving the reactants. Thus, the activation energy can be interpreted as the minimum energy that the reactants must have in order to form the transition state and transform to product molecules. E_a can be calculated from the total energy of the transition state relative to that of the reactants and is achieved when the thermal energy of the reactants overcomes the energy deficit between the energy of the reactants and that of the transition state. The preexponential factor corresponds to the collision frequency and energy of collisions upon which the formation of the transition state is dependent.

For bimolecular reactions, transition state theory yields [139]:

$$k(T) = \frac{1}{(k_B T)h}\gamma(T)K^{\circ}\exp\left(-\Delta G_T^{\ddagger\circ}/RT\right) \tag{16.281}$$

where $\Delta G_T^{\ddagger\circ}$ is the quasi-thermodynamic free energy of activation, $\gamma(T)$ is a transmission coefficient, K° is the reciprocal of the concentration, h is Planck's constant, and k_B is the Boltzmann constant. The factor $\frac{1}{(k_B T)h}$ is obtained by dynamical classical equations of motion involving species trajectories having a statistical mechanical distribution. Specifically, the reactant molecular distribution is typically a Maxwell-Boltzmann distribution. The classical derivation of the preexponential term of the Arrhenius equation can be found in textbooks and review articles such as section 2.4 of Ref. [139]. Typically the A term can be accurately determined from the Maxwell-Boltzmann-distribution-constrained classical equations of motion by sampling or by using Monte Carlo methods on many sets (usually more than ten thousand) of initial conditions for the coordinates and momenta involving the trajectories. The translational levels are a continuous distribution, and the rotational and vibrational levels are quantized according to the classical equations given, for example, in the Vibration of the Hydrogen Molecular Ion section and the Diatomic Molecular Rotation section.

S_N2 REACTION OF Cl^- WITH CH_3Cl

Consider the S_N2 (bimolecular nucleophilic substitution) gas-phase reaction of Cl^- with chloromethane through a transition state:

$$Cl^- + CH_3Cl \rightarrow ClCH_3 + Cl^- \tag{16.282}$$

The corresponding Arrhenius equation for the reaction given by Eq. (16.280) is:

$$k(T) = \frac{k_B T}{h}\frac{Q^{\ddagger}}{\Phi^R}e^{\frac{-\Delta E^{\ddagger}}{k_B T}} \tag{16.283}$$

where k_B is the Boltzmann constant, h is Planck's constant, $\Delta E^{\ddagger}$ is the activation energy of the transition state ‡, T is the temperature, Φ^R is the reaction partition per unit volume, and $Q^{\ddagger}$ is the coordinate independent transition-state partition function. The preexponential factor $\frac{k_B T}{h}\frac{Q^{\ddagger}}{\Phi^R}$ has previously been calculated classically and shown to be in agreement with the experimental rate constant [140]. Then, only the transition state need be calculated and its geometry and energy compared to observations to confirm that classical physics is predictive of reaction kinetics. The activation energy can be calculated by determining the energy at the point that the nascent bond with the chloride ion is the same as that of the leaving chlorine wherein the negative charge is equally distributed on the chlorines. The rearrangement of bonds and the corresponding electron MOs of the reactants and products can be modeled as a continuous transition of the bond orders of the participating bonds from unity to zero and vice versa, respectively, wherein the transition state is a minimum-energy molecule having bonds between all of the reactants, Cl^- and CH_3Cl

TRANSITION STATE

The reaction proceeds by back-side attack of Cl^- on CH_3Cl. Based on symmetry, the reaction pathway passes through a D_{3h} configuration having $Cl^{\delta-}-C-Cl^{\delta-}$ on the C_3 axis. The hydrogen atoms are in the σ_h plane with the bond distances the same as those of the CH_3 functional group given in the Alkyl Chlorides section, since this group is not involved in the substitution reaction. The transition-state group $Cl^{\delta-}-C-Cl^{\delta-}$ is treated as a three-centered-bond functional group that comprises a linear

combination of Cl^- and the $C-Cl$ group of chloromethane ($C-Cl$ (i) given in Table 15.33). It is solved using the Eq. (15.51) with the total energy matched to the sum of the H_2-type ellipsoidal MO total energy, $-31.63536831\ eV$ given by Eq. (11.212) as in the case of chloromethane, and the energy of the two outer electrons of Cl^-, $E\left(Cl^-\right)=-IP_1-IP_2=-12.96764\ eV-3.612724\ eV=-16.58036\ eV$ [15, 141]. These electrons are contributed to form the back-side-attack bond. Then, the corresponding parameter $E_{T(AO/HO)}\ (eV)$ is $-14.63489\ eV-16.58036\ eV=-31.21525\ eV$ due to the match of the MO energy to both $E\left(C,2sp^3\right)=-14.63489\ eV$ (Eq. (15.25)) and $E\left(Cl^-\right)$, and $E_{initial\ (C_5\ AO/HO)}\ (eV)$ is $-16.58036\ eV$ corresponding to the initial energy of the Cl^- electrons. Also, due to the two $C-Cl$ bonds of the $Cl^{\delta-}-C-Cl^{\delta-}$ functional group $n_1=2$. Otherwise all of the parameters of Eq. (15.51) remain the same as those of chloromethane given in Table 15.36. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters are given in Tables 16.53, 16.54, and 16.55, respectively. The color scale, translucent view of the charge density of the chloride-ion-chloromethane transition state comprising the $Cl^{\delta-}-C-Cl^{\delta-}$ functional group is shown in Figure 16.17. The transition state bonding comprises two paired electrons in each $Cl^{\delta-}-C$ MO with two from Cl^-, one from Cl and one from CH_3. As a symmetrical three-centered bond, the central bonding species are two Cl bound to a central CH_3^+ per $Cl^{\delta-}-C$ MO with a continuous current onto the $C-H$ MO at the intersection of each $Cl^{\delta-}-C$ MO with the CH_3^+ group. Due to the four electrons and the valence of the chlorines, the latter possess a partial negative charge of $-0.5e$ distributed on each $Cl^{\delta-}-C$ MO such that the far field is equivalent to that of the corresponding point charge at each Cl nucleus.

Figure 16.17. Color scale, translucent view of the chloride-ion-chloromethane transition state comprising the $Cl^{\delta-}-C-Cl^{\delta-}$ functional group showing the orbitals of the atoms at their radii, the ellipsoidal surface of each H or H_2-type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale).

$E_{D(Group)}\ (eV)$	3.73930	12.49186

The bond energy of the $C-Cl$ group of chloromethane from Table 15.36 is $E_{D(Group)}\ (eV)=3.77116\,eV$ compared to the bond energy of the $Cl^{\delta^-}-C-Cl^{\delta^-}$ functional group of the chloride-ion-chloromethane transition state of

$E_{D(Group)}\ (eV) = 3.73930\ eV$ (Table 16.55). Since the energies of the CH_3 functional groups are unchanged, the chloride-ion-chloromethane transition state is $\Delta E = +0.03186\ eV\ (+0.73473\ kcal/mole)$ higher in energy than chloromethane. Experimentally, the transition state is about $1 \pm 1\ kcal/mole$ higher [137]. Using this energy as the corresponding activation energy $\Delta E^{\ddagger}$ of Eq. (16.283) with the classically determined preexponential factor $\frac{k_B T}{h}\frac{Q^{\ddagger}}{\Phi^R}$ predicts the experimental reaction rate very well [140].

NEGATIVELY-CHARGED MOLECULAR ION COMPLEX $\mathbb{C}$

In addition to the nature and energy of the transition state designated by ‡, experimental gas-phase rate constants indicate that the reaction of Cl^- with CH_3Cl passes through a bound state comprising the attachment of Cl^- to the positive dipole of CH_3Cl [140, 142, 143] (the dipole moment of the $C-Cl$ functional group is given in the Bond and Dipole Moments section). This negatively-charged molecular ion complex designated $\mathbb{C}$ exists as a more stable state in between the reactants and the transition state, and by equivalence of the chlorines, it also exists between the transition state and the products. Experimentally $\mathbb{C}$ is $12.2 \pm 2\ kcal/mole$ more stable than the isolated reactants and products, Cl^- and CH_3Cl. Thus, an energy well corresponding to $\mathbb{C}$ occurs on either side of the energy barrier of the transition state ‡ that is about $1 \pm 1\ kcal/mole$ above the reactants and products [140, 143]. Thus, the combination of the depth of this well and the barrier height yields an intrinsic barrier to nucleophilic substitution given by the reaction of Eq. (16.282) of $13.2 \pm 2.2\ kcal/mole$ [140, 143].

The negatively-charged molecular ion complex $\mathbb{C}$ comprises the functional groups of CH_3Cl ($C-Cl$ (i) and CH_3 given in Table 15.33 of the Alkyl Chlorides section) and a $Cl^-\cdot C^{\delta+}$ functional group wherein Cl^- is bound to the CH_3Cl moiety by an ion-dipole bond. As given in the case of the dipole-dipole bonding of ice, liquid water, and water vapor as well as the van der Waals bonding in graphite and noble gases given in the Condensed Matter Physics section, the bond energy and bond distance of the $Cl^-\cdot C^{\delta+}$ functional group are determined by the limiting energy and distance of the formation of a corresponding nascent $Cl^- - CH_3Cl$ covalent bond that destabilizes the $C-Cl$ bond of the CH_3Cl moiety by involving charge density of its electrons in the formation the nascent bond. Subsequently, the higher energy $Cl^{\delta-} - C - Cl^{\delta-}$ functional group of the transition state is formed.

The energy and geometric parameters of the $Cl^-\cdot C^{\delta+}$ functional group are solved using Eq. (15.51) with the total energy matched to the H_2-type ellipsoidal MO total energy, $-31.63536831\ eV$. The parameter $E_{T(AO/HO)}\ (eV)$ is $-14.63489\ eV - 3.612724\ eV = -18.24761\ eV$ due to the match of the MO energy to both $E\left(C, 2sp^3\right) = -14.63489\ eV$ (Eq. (15.25)) and the outer electron of $E\left(Cl^-\right)$ ($-IP_1 = -3.612724\ eV$) [141] that forms the nascent bond by the involving the electrons of the $C-Cl$ group of the CH_3Cl moiety. Then, $E_{initial(c_5\ AO/HO)}\ (eV)$ is $-3.612724\ eV$ corresponding to the initial energy of the outer Cl^- electron. Also, $E_T\left(atom-atom, msp^3.AO\right)$ in Eq. (15.61) is $-1.85836\ eV$ due to the charge donation from the C HO to the MO based on the energy match between the $C2sp^3$ HOs corresponding to the energy contribution of methylene, $-0.92918\ eV$ (Eq. (14.513)). $E_{mag} = 0$ since the Cl^- electrons are paired upon dissociation, and the vibrational energy of the transition state is appropriate for $Cl^-\cdot C^{\delta+}$. Otherwise, all of the parameters of Eq. (15.51) remain the same as those of chloromethane given in Table 15.36. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters are given in Tables 16.56, 16.57, and 16.58, respectively. The color scale, translucent view of the charge density of the negatively-charged molecular ion complex $\mathbb{C}$ comprising the $Cl^-\cdot C^{\delta+}$ functional group is shown in Figure 16.18. The bonding in the $\mathbb{C}$ complex comprises two paired electrons in the $Cl^-\cdot C^{\delta+}$ MO with 1/2 of the charge density from Cl^- and the other half from CH_3. The central bonding species are a Cl bound to a central CH_3^+ with a continuous current onto the $C-H$ MO at the intersection of the $Cl^-\cdot C^{\delta+}$ MO with the CH_3^+ group. Due to the two electrons and the valence of the chlorine, the latter possess a negative charge of $-e$ distributed on the $Cl^-\cdot C^{\delta+}$ MO such that the far field is equivalent to that of the corresponding point charge at the Cl nucleus. The bonding in the CH_3Cl moiety is equivalent to that of chloromethane except that the $C-H$ bonds are in a plane to accommodate the $Cl^-\cdot C^{\delta+}$ MO.

The bond energies of the CH_3Cl moiety are unchanged to the limit of the formation of the $Cl^{-}\cdot C^{\delta+}$ functional group of the negatively-charged molecular ion complex $\mathbb{C}$. Thus, the energy of stabilization of forming the ion-dipole complex is

equivalent to the bond energy of the $Cl^{-}\cdot C^{\delta+}$ functional group. Experimentally $\mathbb{C}$ is $12.2\pm 2\ kcal/mole$ more stable than the isolated reactants and products [134, 136, 137], Cl^{-} and CH_3Cl. The bond energy of the $Cl^{-}\cdot C^{\delta+}$ functional group of the negatively-charged molecular ion complex $\mathbb{C}$ of $E_D(Group)=12.08900\ kcal/mole\ (0.52422\ eV)$ given in Table 16.58 matches the experimental stabilization energy very well. A simulation of the reaction of Eq. (16.282) is available on the internet [145].

Chapter 17

NATURE OF THE SOLID MOLECULAR BOND OF THE THREE ALLOTROPES OF CARBON

GENERAL CONSIDERATIONS OF THE SOLID MOLECULAR BOND

The solid molecular bond of a material comprising an arbitrary number of atoms can be solved using similar principles and procedures as those used to solve organic molecules of arbitrary length. Molecular solids are also comprised of functional groups. Depending on the material, exemplary groups are $C-C$, $C=C$, $C-O$, $C-N$, $C-S$, and others given in the Organic Molecular Functional Groups and Molecules section. The solutions of these functional groups or any others corresponding to the particular solid can be conveniently obtained by using generalized forms of the geometrical and energy equations given in the Derivation of the General Geometrical and Energy Equations of Organic Chemistry section. The appropriate functional groups with their geometrical parameters and energies can be added as a linear sum to give the solution of any molecular solid.

DIAMOND

It is demonstrated in this Diamond section as well as the Fullerene (C_{60}) and Graphite sections, that very complex macromolecules can be simply solved from the groups at each vertex carbon atom of the structure. Specifically, for fullerene a $C=C$ group is bound to two $C-C$ bonds at each vertex carbon atom of C_{60}. The solution of the macromolecule is given by superposition of the geometrical and energy parameters of the corresponding two groups. In graphite, each sheet of joined hexagons can be constructed with a $C=C$ group bound to two $C-C$ bonds at each vertex carbon atom that hybridize to an aromatic-like functional group, $C \overset{8/3e}{=} C$, with $\frac{8}{3}$ electron-number per bond compared to the pure aromatic functional group, $C \overset{3e}{=} C$, with 3 electron-number per bond as given in the Aromatics section. Similarly, diamond comprising, in principle, an infinite network of carbons can be solved using the functional group solutions where the task is also simple since diamond has only one functional group, the diamond $C-C$ functional group.

The diamond $C-C$ bonds are all equivalent, and each $C-C$ bond can be considered bound to a t-butyl group at the corresponding vertex carbon. Thus, the parameters of the diamond $C-C$ functional group are equivalent to those of the t-butyl $C-C$ group of branched alkanes given in the Branched Alkanes section. Based on symmetry, the parameter R in Eqs. (15.56) and (15.61) is the semimajor axis a, and the vibrational energy in the $\bar{E}_{osc}$ term is that of diamond. Also, the $C2sp^3$ HO magnetic energy E_{mag} given by Eq. (15.67) was subtracted for each t-butyl group of alkyl fluorides, alkyl chlorides, alkyl iodides, thiols, sulfides, disulfides, and nitroalkanes as given in the corresponding sections of Chapter 15 due to a set of unpaired electrons being created by bond breakage. Since each $C-C$ group of diamond bonds with a t-butyl group at each vertex carbon, c_3 of Eq. (15.65) is one, and E_{mag} is given by Eq. (15.67).

The symbol of the functional group of diamond is given in Table 17.1. The geometrical (Eqs. (15.1-15.5) and (15.51)) parameters of diamond are given in Table 17.2. The lattice parameter a_l was calculated from the bond distance using the law of cosines:

$$s_1^2 + s_2^2 - 2s_1 s_2 \text{cosine}\theta = s_3^2 \tag{17.1}$$

With the bond angle $\theta_{\angle CCC} = 109.5°$ [1] and $s_1 = s_2 = 2c'_{C-C}$, the internuclear distance of the $C-C$ bond, $s_3 = 2c'_{C_t-C_t}$, the internuclear distance of the two terminal C atoms is given by:

$$2c'_{C_t-C_t} = \sqrt{2\left(2c'_{C-C}\right)^2\left(1-\text{cosine}\left(109.5°\right)\right)} \tag{17.2}$$

Two times the distance $2c'_{C_t-C_t}$ is the hypotenuse of the isosceles triangle having equivalent sides of length equal to the lattice parameter a_l. Using Eq. (17.2) and $2c'_{C-C} = 1.53635\ \text{Å}$ from Table 17.2, the lattice parameter a_l for the cubic diamond structure is given by:

$$a_l = \frac{2\left(2c'_{C_t-C_t}\right)}{\sqrt{2}} = \sqrt{2}\sqrt{2\left(2c'_{C-C}\right)^2\left(1-\text{cosine}\left(109.5°\right)\right)} = 3.54867\ \text{Å} \tag{17.3}$$

The intercept (Eqs. (15.80-15.87)) and energy (Eqs. (15.6-15.11) and (15.17-15.65)) parameters of diamond are given in Tables 17.2, 17.3, and 17.4, respectively. The total energy of diamond given in Table 17.5 was calculated as the sum over the integer multiple of each $E_{D\,(Group)}$ of Table 17.4 corresponding to functional-group composition of the molecular solid. The experimental $C-C$ bond energy of diamond, $E_{D_{\exp}}(C-C)$ at 298 K, is given by the difference between the enthalpy of formation of gaseous carbon atoms from graphite $\left(\Delta H_f\left(C_{graphite}\left(gas\right)\right)\right)$ and the heat of formation of diamond $\left(\Delta H_f\left(C(diamond)\right)\right)$ wherein graphite has a defined heat of formation of zero $\left(\Delta H_f\left(C\left(graphite\right)=0\right)\right)$:

$$E_{D_{\exp}}(C-C) = \frac{1}{2}\left[\Delta H_f\left(C_{graphite}\left(gas\right)\right) - \Delta H_f\left(C(diamond)\right)\right] \tag{17.4}$$

where the heats of formation of atomic carbon and diamond are [2]:

$$\Delta H_f\left(C_{graphite}\left(gas\right)\right) = 716.68\ kJ/mole\ \left(7.42774\ eV/atom\right) \tag{17.5}$$

$$\Delta H_f\left(C(diamond)\right) = 1.9\ kJ/mole\ \left(0.01969\ eV/atom\right) \tag{17.6}$$

Using Eqs. (17.4-17.6), $E_{D_{\exp}}(C-C)$ is:

$$E_{D_{\exp}}(C-C) = \frac{1}{2}\left[7.42774\ eV - 0.01969\ eV\right] = 3.704\ eV \tag{17.7}$$

where the factor of one half corresponds to the ratio of two electrons per bond and four electrons per carbon atom. The bond angle parameters of diamond determined using Eqs. (15.88-15.117) are given in Table 17.6. The structure of diamond is shown in Figure 17.1.

FULLERENE (C_{60})

C_{60} comprises 60 equivalent carbon atoms that are bound as 60 single bonds and 30 double bonds in the geometric form of a truncated icosahedron: twelve pentagons and twenty hexagons joined such that no two pentagons share an edge. To achieve this minimum energy structure each equivalent carbon atom serves as a vertex incident with one double and two single bonds. Each type of bond serves as a functional group which has aromatic character. The aromatic bond is uniquely stable and requires the sharing of the electrons of multiple H_2-type MOs. The results of the derivation of the parameters of the benzene molecule given in the Benzene Molecule (C_6H_6) section was generalized to any aromatic functional group of aromatic and heterocyclic compounds in the Aromatic and Heterocyclic Compounds section. Ethylene serves as a basis element for the $C\overset{3e}{=}C$ bonding of the aromatic bond wherein each of the $C\overset{3e}{=}C$ aromatic bonds comprises $(0.75)(4)=3$ electrons according to Eq. (15.161) wherein C_2 of Eq. (15.51) for the aromatic $C\overset{3e}{=}C$-bond MO given by Eq. (15.162) is $C_2\left(aromaticC2sp^3HO\right)=c_2\left(aromaticC2sp^3HO\right)=0.85252$ and $E_T\left(atom-atom,msp^3.AO\right)=-2.26759\ eV$. In C_{60}, the minimum energy structure with equivalent carbon atoms wherein each carbon forms bonds with three other such carbons requires a redistribution of charge within an aromatic system of bonds. The $C=C$ functional group of C_{60} comprises the aromatic bond with the exception that it comprises four electrons. Thus, $E_T\,(Group)$ and $E_D\,(Group)$ are given by Eqs. (15.165) and (15.166), respectively, with $f_1=1$, $c_4=4$, and $\bar{E}_{Kvib}\ (eV)$ is that of C_{60}.

In addition to the $C=C$ bond, each vertex carbon atom of C_{60} is bound to two $C-C$ bonds that substitute for the aromatic $C\overset{3e}{=}C$ and $C-H$ bonds. As in the case of the $C-C$-bond MO of naphthalene, to match energies within the MO that bridges single and double-bond MOs, $E\left(AO/HO\right)$ and $\Delta E_{H_2MO}\left(AO/HO\right)$ in Eq. (15.51) are $-14.63489\ eV$ and $-2.26759\ eV$, respectively.

To meet the equipotential condition of the union of the $C2sp^3$ HOs of the $C-C$ single bond bridging double bonds, the parameters c_1, C_2, and C_{2o} of Eq. (15.51) are one for the $C-C$ group, C_{1o} and C_1 are 0.5, and c_2 given by Eq. (13.430) is $c_2\left(C2sp^3HO\right)=0.91771$. To match the energies of the functional groups with the electron-density shift to the double bond, $E_T\left(atom-atom,msp^3.AO\right)$ of each of the equivalent $C-C$-bond MOs in Eq. (15.61) due to the charge donation from the C atoms to the MO can be considered a linear combination of that of $C-C$-bond MO of toluene, $-1.13379\ eV$ and that of the aromatic $C-H$-bond MO, $\frac{-1.13379\ eV}{2}$. Thus, $E_T\left(atom-atom,msp^3.AO\right)$ of each $C-C$-bond MO of C_{60} is $\frac{-1.13379\ eV+0.5\left(-1.13379\ eV\right)}{2}=0.75\left(-1.13379\ eV\right)=-0.85034\ eV$. As in the case of the aromatic $C-H$ bond, $c_3=1$ in Eq. (15.65) with E_{mag} given by Eq. (15.67), and $\bar{E}_{Kvib}\ (eV)$ is that of C_{60}.

The symbols of the functional groups of C_{60} are given in Table 17.7. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of C_{60} are given in Tables 17.8, 17.9, and 17.10, respectively. The total energy of C_{60} given in Table 17.11 was calculated as the sum over the integer multiple of each $E_D\,(Group)$ of Table 17.10 corresponding to functional-group composition of the molecule. The bond angle parameters of C_{60} determined using Eqs. (15.87-15.117) are given in Table 17.12. The structure of C_{60} is shown in Figures 17.2A and B. The fullerene vertex-atom group comprising a double and two single bonds can serve as a basis element to form other higher-order fullerene-type macromolecules, hyperfullerenes, and complex hybrid conjugated carbon and aromatic structures comprising a mixture of elements from the group of fullerene, graphitic, and diamond carbon described in the corresponding sections.

Figure 17.2. C_{60} MO comprising a hollow cage of sixty carbon atoms bound with the linear combination of sixty sets of $C-C$-bond MOs bridged by 30 sets of $C=C$-bond MOs. A $C=C$ group is bound to two $C-C$ groups at each vertex carbon atom of C_{60}. Color scale, translucent pentagonal view (A), and hexagonal view (B), of the charge-density of the C_{60}-bond MO with each $C2sp^3$ HO shown transparently. For each $C-C$ and $C=C$ bond, the ellipsoidal surface of the H_2-type ellipsoidal MO that transitions to the $C2sp^3$ HO, the $C2sp^3$ HO shell, inner most $C1s$ shell, and the nuclei (red, not to scale), are shown.

FULLERENE DIHEDRAL ANGLES

For C_{60}, the bonding at each vertex atom C_b comprises two single bonds, $C_a - C_b - C_a$, and a double bond, $C_b = C_c$. The dihedral angle $\theta_{\angle C=C/C-C-C}$ between the plane defined by the $C_a - C_b - C_a$ moiety and the line defined by the corresponding $C_b = C_c$ moiety is calculated using the results given in Table 17.12 and Eqs. (15.114-15.117). The distance d_1 along the bisector of $\theta_{\angle C_a - C_b - Ca}$ from C_b to the internuclear-distance line between one C_a and the other C_a, $2c'_{C_a - C_a}$, is given by:

$$d_1 = 2c'_{C_b - C_a} \cos\frac{\theta_{\angle C_a - C_b - Ca}}{2} = 2.74663a_0 \cos\frac{108.00°}{2} = 1.61443a_0 \tag{17.8}$$

where $2c'_{C_b - C_a}$ is the internuclear distance between C_b and C_a. The atoms C_a, C_a, and C_c define the base of a pyramid. Then, the pyramidal angle $\theta_{\angle C_a C_c C_a}$ can be solved from the internuclear distances between C_c and C_a, $2c'_{C_c - C_a}$, and between C_a and C_a, $2c'_{C_a - C_a}$, using the law of cosines (Eq. (15.115)).

$$\begin{aligned}\theta_{\angle C_a C_b C_a} &= \cos^{-1}\left(\frac{\left(2c'_{C_c - C_a}\right)^2 + \left(2c'_{C_c - C_a}\right)^2 - \left(2c'_{C_a - C_a}\right)^2}{2\left(2c'_{C_c - C_a}\right)\left(2c'_{C_c - C_a}\right)}\right) = \cos^{-1}\left(\frac{\left(4.65618\mathrm{a}_0\right)^2 + \left(4.65618\mathrm{a}_0\right)^2 - \left(4.4441\mathrm{a}_0\right)^2}{2\left(4.65618\mathrm{a}_0\right)\left(4.65618\mathrm{a}_0\right)}\right) \\ &= 57.01°\end{aligned} \tag{17.9}$$

Then, the distance d_2 along the bisector of $\theta_{\angle C_a C_c C_a}$ from C_c to the internuclear-distance line $2c'_{C_a - C_a}$, is given by:

$$d_2 = 2c'_{C_c - C_a} \cos\frac{\theta_{\angle C_a C_c C_a}}{2} = 4.65618a_0 \cos\frac{57.01°}{2} = 4.09176a_0 \tag{17.10}$$

The lengths d_1, d_2, and $2c'_{C_b = C_c}$ define a triangle wherein the angle between d_1 and the internuclear distance between C_b and C_c, $2c'_{C_b = C_c}$, is the dihedral angle $\theta_{\angle C=C/C-C-C}$ that can be solved using the law of cosines (Eq. (15.117)).

$$\begin{aligned}\theta_{\angle C=C/C-C-C} &= \cos^{-1}\left(\frac{d_1^2 + \left(2c'_{C_b = C_c}\right)^2 - d_2^2}{2d_1\left(2c'_{C_b = C_c}\right)}\right) = \cos^{-1}\left(\frac{\left(1.61443\mathrm{a}_0\right)^2 + \left(2.62936\mathrm{a}_0\right)^2 - \left(4.09176\mathrm{a}_0\right)^2}{2\left(1.61443\mathrm{a}_0\right)\left(2.62936\mathrm{a}_0\right)}\right) \\ &= 148.29°\end{aligned} \tag{17.11}$$

The dihedral angle for a truncated icosahedron corresponding to $\theta_{\angle C=C/C-C-C}$ is:

$$\theta_{\angle C=C/C-C-C} = 148.28° \tag{17.12}$$

The dihedral angle $\theta_{\angle C-C/C-C=C}$ between the plane defined by the $C_a - C_b = C_c$ moiety and the line defined by the corresponding $C_b - C_a$ moiety is calculated using the results given in Table 17.12 and Eqs. (15.118-15.127). The parameter d_1 is the distance from C_b to the internuclear-distance line between C_a and C_c, $2c'_{C_a - C_c}$. The angle between d_1 and the $C_b - C_a$ bond, $\theta_{\angle C_a C_b d_1}$, can be solved reiteratively using Eq. (15.121).

$$\begin{aligned}&\left(2c'_{C_b - C_a}\right)^2 + \left(\frac{\left(2c'_{C_b - C_a}\right)^2 - \left(2c'_{C_b - C_c}\right)^2}{2\left(\left(2c'_{C_b - C_a}\right)\mathrm{cosine}\,\theta_{\angle C_a C_b d_1} - \left(2c'_{C_b - C_c}\right)\mathrm{cosine}\left(\theta_{\angle C_a C_b C_c} - \theta_{\angle C_a C_b d_1}\right)\right)}\right)^2 \\ &-2\left(2c'_{C_b - C_a}\right)\left(\frac{\left(2c'_{C_b - C_a}\right)^2 - \left(2c'_{C_b - C_c}\right)^2}{2\left(\begin{array}{l}\left(2c'_{C_b - C_a}\right)\mathrm{cosine}\,\theta_{\angle C_a C_b d_1} \\ -\left(2c'_{C_b - C_c}\right)\mathrm{cosine}\left(\theta_{\angle C_a C_b C_c} - \theta_{\angle C_a C_b d_1}\right)\end{array}\right)}\right)\mathrm{cosine}\,\theta_{\angle C_a C_b d_1} \\ &-\left(\frac{2c'_{C_a - C_c}}{2}\right)^2 = 0 \\ &\left(2.74663\mathrm{a}_0\right)^2 + \left(\frac{\left(2.74663\mathrm{a}_0\right)^2 - \left(2.62936\mathrm{a}_0\right)^2}{2\left(\left(2.74663\mathrm{a}_0\right)\mathrm{cosine}\,\theta_{\angle C_a C_b d_1} - \left(2.62936\mathrm{a}_0\right)\mathrm{cosine}\left(120.00° - \theta_{\angle C_a C_b d_1}\right)\right)}\right)^2 \\ &-\left(\begin{array}{l}2\left(2.74663\mathrm{a}_0\right)\left(\frac{\left(2.74663\mathrm{a}_0\right)^2 - \left(2.62936\mathrm{a}_0\right)^2}{2\left(\begin{array}{l}\left(2.74663\mathrm{a}_0\right)\mathrm{cosine}\,\theta_{\angle C_a C_b d_1} \\ -\left(2.62936\mathrm{a}_0\right)\mathrm{cosine}\left(120.00° - \theta_{\angle C_a C_b d_1}\right)\end{array}\right)}\right)\mathrm{cosine}\,\theta_{\angle C_a C_b d_1}\end{array}\right) = 0 \\ &-\left(\frac{4.6562\mathrm{a}_0}{2}\right)^2\end{aligned} \tag{17.13}$$

The solution of Eq. (17.13) is:

$$\theta_{\angle C_aC_ad_2} = 57.810° \tag{17.14}$$

Eq. (17.14) can be substituted into Eq. (15.120) to give d_1:

$$\begin{aligned} d_1 &= \frac{\left(2c'_{C_b-C_a}\right)^2 - \left(2c'_{C_b-C_c}\right)^2}{2\left(\left(2c'_{C_b-C_a}\right)\text{cosine}\,\theta_{\angle C_aC_bd_1} - \left(2c'_{C_b-C_c}\right)\text{cosine}\left(\theta_{\angle C_aC_bC_c} - \theta_{\angle C_aC_bd_1}\right)\right)} \\ &= \frac{\left(2.74663\text{a}_0\right)^2 - \left(2.62936\text{a}_0\right)^2}{2\left(\left(2.74663\text{a}_0\right)\text{cosine}\left(57.810°\right) - \left(2.62936\text{a}_0\right)\text{cosine}\left(120.00° - 57.810°\right)\right)} = 1.33278\text{a}_0 \end{aligned} \tag{17.15}$$

The atoms C_a, C_a, and C_c define the base of a pyramid. Then, the pyramidal angle $\theta_{\angle C_aC_aC_c}$ can be solved from the internuclear distances between C_a and C_a, $2c'_{C_a-C_a}$, and between C_a and C_c, $2c'_{C_a-C_c}$, using the law of cosines (Eq. (15.115)).

$$\begin{aligned} \theta_{\angle C_aC_aC_c} &= \cos^{-1}\left(\frac{\left(2c'_{C_a-C_a}\right)^2 + \left(2c'_{C_a-C_c}\right)^2 - \left(2c'_{C_a-C_c}\right)^2}{2\left(2c'_{C_a-C_a}\right)\left(2c'_{C_a-C_c}\right)}\right) \\ &= \cos^{-1}\left(\frac{\left(4.44410\text{a}_0\right)^2 + \left(4.65618\text{a}_0\right)^2 - \left(4.65618\text{a}_0\right)^2}{2\left(4.44410\text{a}_0\right)\left(4.65618\text{a}_0\right)}\right) = 61.50° \end{aligned} \tag{17.16}$$

The parameter d_2 is the distance from C_a to the bisector of the internuclear-distance line between C_a and C_c, $2c'_{C_a-C_c}$. The angle between d_2 and the $C_a - C_a$ axis, $\theta_{\angle C_aC_ad_2}$, can be solved reiteratively using Eq. (15.126).

$$\begin{aligned} &\left(2c'_{C_a-C_a}\right)^2 + \left(\frac{\left(2c'_{C_a-C_a}\right)^2 - \left(2c'_{C_a-C_c}\right)^2}{2\left(\left(2c'_{C_a-C_a}\right)\text{cosine}\,\theta_{\angle C_aC_ad_2} - \left(2c'_{C_a-C_c}\right)\text{cosine}\left(\theta_{\angle C_aC_aC_c} - \theta_{\angle C_aC_ad_2}\right)\right)}\right)^2 \\ &-2\left(2c'_{C_b-C_a}\right)\left(\frac{\left(2c'_{C_a-C_a}\right)^2 - \left(2c'_{C_a-C_c}\right)^2}{2\left(\begin{array}{l}\left(2c'_{C_a-C_a}\right)\text{cosine}\,\theta_{\angle C_aC_ad_2} \\ -\left(2c'_{C_a-C_c}\right)\text{cosine}\left(\theta_{\angle C_aC_aC_c} - \theta_{\angle C_aC_ad_2}\right)\end{array}\right)}\right)\text{cosine}\,\theta_{\angle C_aC_bd_1} \\ &-\left(\frac{2c'_{C_a-C_c}}{2}\right)^2 = 0 \\ &\left(4.44410\text{a}_0\right)^2 + \left(\frac{\left(4.44410\text{a}_0\right)^2 - \left(4.65618\text{a}_0\right)^2}{2\left(\left(4.44410\text{a}_0\right)\text{cosine}\,\theta_{\angle C_aC_ad_2} - \left(4.65618\text{a}_0\right)\text{cosine}\left(61.50° - \theta_{\angle C_aC_ad_2}\right)\right)}\right)^2 \\ &-\left(2\left(4.44410\text{a}_0\right)\left(\frac{\left(4.44410\text{a}_0\right)^2 - \left(4.65618\text{a}_0\right)^2}{2\left(\begin{array}{l}\left(4.44410\text{a}_0\right)\text{cosine}\,\theta_{\angle C_aC_ad_2} \\ -\left(4.65618\text{a}_0\right)\text{cosine}\left(61.50° - \theta_{\angle C_aC_ad_2}\right)\end{array}\right)}\right)\text{cosine}\,\theta_{\angle C_aC_ad_2}\right) \\ &-\left(\frac{4.6562\text{a}_0}{2}\right)^2 = 0 \end{aligned} \tag{17.17}$$

The solution of Eq. (17.17) is:

$$\theta_{\angle C_aC_ad_2} = 31.542° \tag{17.18}$$

Eq. (17.18) can be substituted into Eq. (15.125) to give d_2:

$$\begin{aligned} d_2 &= \frac{\left(2c'_{C_a-C_a}\right)^2 - \left(2c'_{C_a-C_c}\right)^2}{2\left(\left(2c'_{C_a-C_a}\right)\text{cosine}\,\theta_{\angle C_aC_ad_2} - \left(2c'_{C_a-C_c}\right)\text{cosine}\left(\theta_{\angle C_aC_aC_c} - \theta_{\angle C_aC_ad_2}\right)\right)} \\ &= \frac{\left(4.44410\text{a}_0\right)^2 - \left(4.65618\text{a}_0\right)^2}{2\left(\left(4.44410\text{a}_0\right)\text{cosine}\left(31.542°\right) - \left(4.65618\text{a}_0\right)\text{cosine}\left(61.50° - 31.542°\right)\right)} = 3.91101\text{a}_0 \end{aligned} \tag{17.19}$$

The lengths d_1, d_2, and $2c'_{C_b-C_a}$ define a triangle wherein the angle between d_1 and the internuclear distance between C_b and C_a, $2c'_{C_b-C_a}$, is the dihedral angle $\theta_{\angle C-C/C-C=C}$ that can be solved using the law of cosines (Eq. (15.117)).

$$\theta_{\angle C-C/C-C=C} = \cos^{-1}\left(\frac{d_1^2+\left(2c'_{C_b-C_a}\right)^2-d_2^2}{2d_1\left(2c'_{C_b-C_a}\right)}\right) = \cos^{-1}\left(\frac{\left(1.33278a_0\right)^2+\left(2.74663a_0\right)^2-\left(3.91101a_0\right)^2}{2\left(1.33278a_0\right)\left(2.74663a_0\right)}\right)=144.71^\circ \tag{17.20}$$

The dihedral angle for a truncated icosahedron corresponding to $\theta_{\angle C-C/C-C=C}$ is:

$$\theta_{\angle C-C/C-C=C}=144.24^\circ \tag{17.21}$$

GRAPHENE AND GRAPHITE

In addition to fullerene and diamond described in the corresponding sections, graphite is the third allotrope of carbon. It comprises planar sheets of covalently bound carbon atoms arranged in hexagonal aromatic rings of a macromolecule of indefinite size. Each sheet comprises graphene. The sheets, in turn, are bound together by weaker intermolecular forces. It was demonstrated in the Fullerene (C_{60}) section, that a very complex macromolecule, fullerene, could be simply solved from the groups at each vertex carbon atom of the structure. Specifically, a $C=C$ group is bound to two $C-C$ bonds at each vertex carbon atom of C_{60}. The solution of the macromolecule is given by superposition of the geometrical and energy parameters of the corresponding two groups. Similarly, diamond comprising, in principle, an infinite network of carbons was also solved in the Diamond section using the functional group solutions, the diamond $C-C$ functional group which is the only functional group of diamond.

The structure of the indefinite network of aromatic hexagons of a sheet of graphite can also be solved by considering the vertex atom. As in the case of fullerene, each sheet of joined hexagons can be constructed with a $C=C$ group bound to two $C-C$ bonds at each vertex carbon atom of graphite. However, an alternative bonding to that of C_{60} is possible for graphite due to the structure comprising repeating hexagonal units. In this case, the lowest energy structure is achieved with a single functional group, one which has aromatic character. The aromatic bond is uniquely stable and requires the sharing of the electrons of multiple H_2-type MOs. The results of the derivation of the parameters of the benzene molecule given in the Benzene Molecule (C_6H_6) section was generalized to any aromatic functional group of aromatic and heterocyclic compounds in the Aromatic and Heterocyclic Compounds section. Ethylene serves as a basis element for the $C\overset{3e}{=}C$ bonding of the aromatic bond wherein each of the $C\overset{3e}{=}C$ aromatic bonds comprises $(0.75)(4)=3$ electrons according to Eq. (15.161) wherein C_2 of Eq. (15.51) for the aromatic $C\overset{3e}{=}C$-bond MO given by Eq. (15.162) is $C_2\left(aromaticC2sp^3HO\right)=c_2\left(aromaticC2sp^3HO\right)=0.85252$ and $E_T\left(atom-atom,msp^3.AO\right)=-2.26759\ eV$.

In graphite, the minimum energy structure with equivalent carbon atoms wherein each carbon forms bonds with three other such carbons requires a redistribution of charge within an aromatic system of bonds. Considering that each carbon contributes four bonding electrons, the sum of electrons of a vertex-atom group is four from the vertex atom plus two from each of the two atoms bonded to the vertex atom where the latter also contribute two each to the juxtaposed group. These eight electrons are distributed equivalently over the three bonds of the group such that the electron number assignable to each bond is $\frac{8}{3}$. Thus, the $C\overset{8/3e}{=}C$ functional group of graphite comprises the aromatic bond with the exception that the electron-number per bond is $\frac{8}{3}$. $E_T(Group)$ and $E_D(Group)$ are given by Eqs. (15.165) and (15.166), respectively, with $f_1=\frac{2}{3}$ and $c_4=\frac{8}{3}$. As in the case of diamond comprising equivalent carbon atoms, the $C2sp^3$ HO magnetic energy E_{mag} given by Eq. (15.67) was subtracted due to a set of unpaired electrons being created by bond breakage such that c_3 of Eqs. (15.165) and (15.166) is one.

The symbol of the functional group of graphite is given in Table 17.13. The geometrical (Eqs. (15.1-15.5) and (15.51)), intercept (Eqs. (15.80-15.87)), and energy (Eqs. (15.6-15.11), (15.17-15.65), and (15.165-15.166)) parameters of graphite are given in Tables 17.14, 17.15, and 17.16, respectively. The total energy of graphite given in Table 17.17 was calculated as the sum over the integer multiple of each $E_D(Group)$ of Table 17.16 corresponding to functional-group composition of the molecular solid. The experimental $C\overset{8/3e}{=}C$ bond energy of graphite at 0 K, $E_{D_{\exp}}\left(C\overset{8/3e}{=}C\right)$, is given by the difference between the enthalpy of formation of gaseous carbon atoms from graphite, $\Delta H_f\left(C_{graphite}(gas)\right)$, and the interplanar binding energy, E_x, wherein graphite solid has a defined heat of formation of zero ($\Delta H_f\left(C(graphite)\right)=0$):

$$E_{D_{\exp}}\left(C\overset{8/3e}{=}C\right)=\frac{2}{3}\left[\Delta H_f\left(C_{graphite}(gas)\right)-E_x\right] \tag{17.22}$$

The factor of $\frac{2}{3}$ corresponds to the ratio of $\frac{8}{3}$ electrons per bond and 4 electrons per carbon atom. The heats of formation of atomic carbon from graphite [9] and E_x [10] are:

$$\Delta H_f\left(C_{graphite}\left(gas\right)\right) = 711.185\ kJ/mole\ \left(7.37079\ eV/atom\right) \tag{17.23}$$

$$E_x = 0.0228\ eV/atom \tag{17.24}$$

Using Eqs. (17.21-17.23), $E_{D_{\exp}}\left(C \overset{8/3e}{=} C\right)$ is:

$$E_{D_{\exp}}\left(C \overset{8/3e}{=} C\right) = \frac{2}{3}\left[7.37079\ eV - 0.0228\ eV\right] = 4.89866\ eV \tag{17.25}$$

The bond angle parameters of graphite determined using Eqs. (15.87-15.117) are given in Table 17.18. The inter-plane distance for graphite of 3.5Å is calculated in the Geometrical Parameters Due to the Interplane van der Waals Cohesive Energy of Graphite section. The structure of graphite is shown in Figure 17.3A and B. The graphite $C \overset{8/3e}{=} C$ functional group can serve as a basis element to form additional complex polycyclic aromatic carbon structures such as nanotubes [11-15].

Chapter 18

NATURE OF THE IONIC BOND OF ALKALI HYDRIDES AND HALIDES

ALKALI-HYDRIDE CRYSTAL STRUCTURES

The alkali hydrides are lithium hydride (LiH), sodium hydride (NaH), potassium hydride (KH), rubidium hydride (RbH), and cesium hydride (CsH). These saline or salt-like alkali-metal hydrides each comprise an equal number of alkali cations and hydride ions [1] in unit cells of a crystalline lattice. The crystal structure of these ionic compounds is the face-centered cubic $NaCl$ structure [2]. This close-packed structure is expected since it gives the optimal approach of the positive and negative ions [3]. The structure comprises face-centered cubes of both M^+ and H^- ions combined, but offset by half a unit cell length in one direction so that M^+ ions are centered in the edges of the H^- lattice and vice versa. Each M^+ is surrounded by six nearest neighbor H^- ions and vice versa. The resulting unit cell consists of anions (or cations) at the midpoint of each edge and at the center of the cell such that the unit cell contains four cations and four anions.

The interionic radius of each hydride can be derived by considering the radii of the alkali ion and the hydride ion, the electron energies at these radii, and the conditions for stability of the ions as the internuclear distance changes and the ions are mutually influenced by Coulombic forces. Then, the lattice energy is given by the sum over the crystal of the minimum energy of the interacting ion pairs at the radius of minimum approach for which the ions are stable. The sum is further over all Coulombic interactions of the ions of the crystal.

Each hydride MH ($M = Li, Na, K, Rb, Cs$) is comprised of M^+ and H^- ions. From Coulomb's Law, the lattice energy ΔU for point charges is given by the Born-Mayer equation [3]

$$\Delta U = NM_c Z_+ Z_- \frac{e^2}{4\pi\varepsilon_0 r_0}\left(1-\frac{\rho}{r_0}\right) \tag{18.1}$$

where N is Avogadro's number, M_c is the Madelung constant (the convergent sum of all Coulombic interactions of any given ion with the lattice of ions), Z_+ and Z_- are the ionic charges in elementary charge units, r_0 is the distance between ion centers, and ρ is a constant that corrects for higher-order terms (e.g. $1/r_0^6$ to $1/r_0^{12}$ terms) in repulsion between close neighbor ions. The $M\text{—}H$ distance can be calculated from the minimum energy packing of the ions, which is stable. Each ion is surrounded in a symmetrical octahedral field of six counterions. From Eq. (18.1), the lattice energy increases as the interionic distance decreases. But, the interionic distance cannot be the sum of the contact radii. This is easily appreciated by considering that the energies of the outer electron of M^+ and the outer two electrons of H^- are very different. For sufficiently small interionic distances, the most energetic reaction that can occur which eliminates the cation and consequently the lattice energy is the following :

$$M^+ + e^- \rightarrow M \tag{18.2}$$

For shorter distances, the spherically symmetrical ${}^1S_0$ state of the hydride ion is distorted by M^+, and it is not stable in the ionic crystal when the $M\text{—}H$ distance is given by the condition that the total Coulombic energy of attractive terms of H^- in the field of M^+ as well as the repulsive terms between like-charged ions is equal to the binding energy of M, $BE(M)$, for the cations of the crystal. Then, the lattice energy is given by the product of Avogadro's number, $BE(M)$, and the Madelung constant which takes into account all inverse r_0 (point-like) Coulombic interactions of the crystal:

$$\Delta U = NM_c BE(M) \tag{18.3}$$

Thus, M_c is the factor of stability of forming the crystal from M^+ and H^- ions. The value for the $NaCl$ structure is $M_c = 1.74756$ [3].

Since the Coulombic potential of the ions is equivalent to that of point charges with some higher order ion-ion-interaction repulsive terms, the $M — H$ distance $r_0(MH)$ given using Eq. (18.1), Eq. (18.3), and $BE(M)$ is:

$$r_0(MH) = \frac{\frac{Z_+Z_-e^2}{BE(M)4\pi\varepsilon_0} + \sqrt{\left(\frac{Z_+Z_-e^2}{BE(M)4\pi\varepsilon_0}\right)^2 - \frac{4\rho Z_+Z_-e^2}{BE(M)4\pi\varepsilon_0}}}{2} \tag{18.4}$$

wherein $\rho = 0.4\ X\ 10^{-10}\ m$ for alkali hydrides [4-5]. The parameters of the hydride ion are given in the corresponding section.

LITHIUM HYDRIDE

The calculated ionic radii for Li^+ and H^- ions given in Tables 7.1 and 7.2 are $0.35566a_0$ and $1.8660a_0$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of Li^+ (Eqs. (7.35), (7.45-7.46), and (7.63)) and H^- (Eq. (7.69)) are $75.665\ eV$ and $0.75471\ eV$, respectively. Furthermore, since the calculated ionization energy (Eq. (10.25)) of Li to Li^+ is $5.40381\ eV$ as shown in Table 10.1 and the ionization energy (Eq. (7.69)) of H^- to H is $0.75471\ eV$ $(1.20836\ X\ 10^{-19}\ J)$, for sufficiently small interionic distances, the lithium ion may be reduced.

Substitution of $BE(Li) = 8.65786\ X\ 10^{-19}\ J$ into Eq. (18.3) gives the calculated lattice energy of

$$\Delta U = NM_cBE(Li) = 1.74756N8.65786\ X\ 10^{-19}\ J = 911.1\ kJ/mole\ (217.8\ kcal/mole) \tag{18.5}$$

This agrees well with the experimental lattice energy of $\Delta U = 217.95\ kcal/mole$ [1] and confirms that the ionic compound LiH comprises a precise packing of discrete ions.

The calculated radius of Li (Eq. (10.13)) given in Table 10.1 is $2.55606a_0$, and the calculated binding energy is $5.40381\ eV$ $(8.65786\ X\ 10^{-19}\ J)$ (Eq. (10.25)). The $Li — H$ distance, $r_0(LiH)$, calculated using Eq. (18.4) with the substitution of $BE(Li) = 8.65786\ X\ 10^{-19}\ J$ is:

$$r_0(LiH) = 2.17\ X\ 10^{-10}\ m \tag{18.6}$$

The calculated $Li — H$ is in reasonable agreement with the experimental distance of $r_0(LiH) = 2.04\ X\ 10^{-10}\ m$ [1] given the experimental difficulty of performing X-ray diffraction on lithium and hydrogen due to the low electron densities. Furthermore, there is a 15% variation in experimental measurements of the density of LiH [1] that affects the internuclear spacing. Using the $Li — H$ distance and the calculated ionic radii, the lattice structure of LiH is shown in Figure 18.1A.

SODIUM HYDRIDE

The calculated ionic radii for Na^+ and H^- ions given in Tables 10.8 and 7.2 are $0.560945a_0$ and $1.8660a_0$, respectively. But, the interionic distance can not be the sum of the contact radii since the calculated ionization energies of Na^+ (Eqs. (10.212-10.213)) and H^- (Eq. (7.69)) are $48.5103\ eV$ and $0.75471\ eV$, respectively. Furthermore, since the calculated ionization energy (Eqs. (10.226-10.227)) of Na to Na^+ is $5.12592\ eV$ as shown in Table 10.10 and the ionization energy (Eq. (7.69)) of H^- to H is $0.75471\ eV$ $(1.20836\ X\ 10^{-19}\ J)$, for sufficiently small interionic distances, the sodium ion may be reduced.

Substitution of $BE(Na) = 8.21263\ X\ 10^{-19}\ J$ into Eq. (18.3) gives the calculated lattice energy of

$$\Delta U = NM_cBE(Na) = 1.74756N8.21263\ X\ 10^{-19}\ J = 864.3\ kJ/mole\ (206.6\ kcal/mole) \tag{18.7}$$

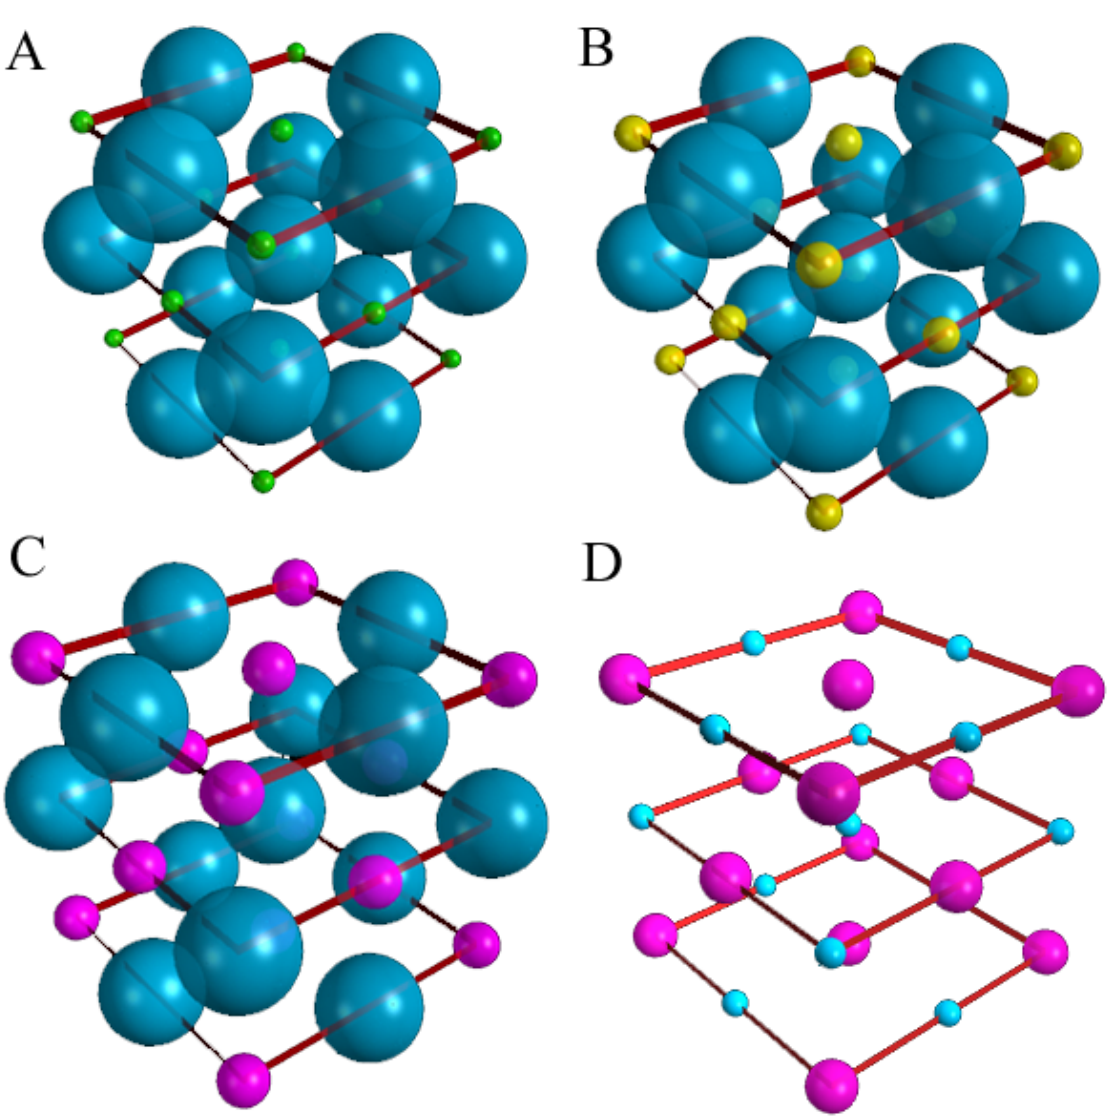
This agrees well with the experimental lattice energy of $\Delta U = 202.0\ kcal/mole$ [2] and confirms that the ionic compound NaH comprises a precise packing of discrete ions.

The calculated radius of Na (Eq. (10.226)) given in Table 10.10 is $2.65432a_0$, and the calculated binding energy is $5.12592\ eV$ $(8.21263\ X\ 10^{-19}\ J)$ (Eqs. (10.226-10.227)). The $Na — H$ distance, $r_0(NaH)$, calculated using Eq. (18.4) with the substitution of $BE(Na) = 8.21263\ X\ 10^{-19}\ J$ is:

$$r_0(NaH) = 2.33\ X\ 10^{-10}\ m \tag{18.8}$$

The calculated $Na — H$ is in good agreement with the experimental distance of $r_0(NaH) = 2.44\ X\ 10^{-10}\ m$ [2]. Using the $Na — H$ distance and the calculated ionic radii, the lattice structure of NaH is shown in Figure 18.1B.

(B) The crystal structure of NaH. (C) The crystal structure of KH. (D) The crystal structure of $KH\left(\frac{1}{4}\right)$.



POTASSIUM HYDRIDE

The calculated ionic radii for K^+ and H^- ions given in Tables 10.17 and 7.2 are $0.85215a_0$ and $1.8660a_0$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of K^+ (Eqs. (10.399-10.400)) and H^- (Eq. (7.69)) are $31.9330\ eV$ and $0.75471\ eV$, respectively. Furthermore, since the calculated ionization energy (Eqs. (10.414-10.415)) of K to K^+ is $4.33\ eV$ as shown in Table 10.19 and the ionization energy (Eq. (7.69)) of H^- to H is $0.75471\ eV$ $(1.20836\ X\ 10^{-19}\ J)$, for sufficiently small interionic distances, the potassium ion may be reduced.

Substitution of $BE(K) = 6.93095\ X\ 10^{-19}\ J$ into Eq. (18.3) gives the calculated lattice energy of:

$$\Delta U = NM_c BE(K) = 1.74756N6.93095\ X\ 10^{-19}\ J = 729.4\ kJ/mole\ (174.3\ kcal/mole) \tag{18.9}$$

This agrees well with the experimental lattice energy of $\Delta U = 177.2\ kcal/mole$ [2] and confirms that the ionic compound KH comprises a precise packing of discrete ions.

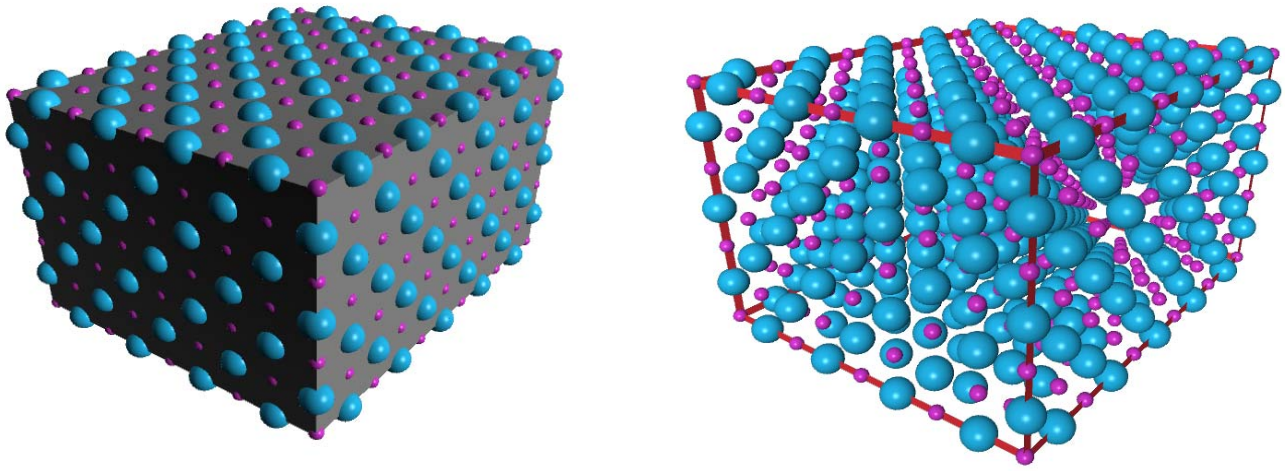
The calculated radius of K (Eq. (10.414)) given in Table 10.19 is $3.14515a_0$, and the calculated binding energy is $4.32596\ eV$ $(6.93095\ X\ 10^{-19}\ J)$ (Eqs. (10.414-10.415)). The $K-H$ distance, $r_0(KH)$, calculated using Eq. (18.4) with the substitution of $BE(K) = 6.93095\ X\ 10^{-19}\ J$ is:

$$r_0(KH) = 2.86\ X\ 10^{-10}\ m \tag{18.10}$$

The calculated $K-H$ is in good agreement with the experimental distance of $r_0(KH) = 2.85\ X\ 10^{-10}\ m$ [2]. Using the $K-H$ distance and the calculated ionic radii, the lattice structure of KH is shown in Figure 18.1C. An aggregate crystal of unit cells is shown in Figure 18.2.

Figure 18.2. The crystal structure of KH. (K^+= purple and H^-= blue). (A) Opaque view showing the external geometrical crystal structure of an aggregate of unit cells of KH. (B) The crystal structure of KH showing an aggregate of units cells.

A **B**



RUBIDIUM AND CESIUM HYDRIDE

As further tests of the boundary condition, the lattice energies of RbH and CsH are given by the product of Avogadro's number, the Madelung constant of $M_c = 1.74756$, and the binding energy of Rb and Cs of $4.17713\ eV$ and $3.89390\ eV$ [6], respectively. Using Eq. (18.3), the calculated lattice energy of RbH is:

$$\Delta U = 1.74756N(e4.17713\ eV) = 704.3\ kJ/mole = 168.3\ kcal/mole \tag{18.11}$$

This agrees well with the experimental lattice energy of $\Delta U = 168.6\ kcal/mole$ [2] and confirms that the ionic compound RbH comprises a precise packing of discrete ions.

Substitution of $BE(Rb) = 6.6925\ X\ 10^{-19}\ J$ into Eq. (18.4) gives the $Rb-H$ distance $r_0(RbH)$:

$$r_0(RbH) = 2.99\ X\ 10^{-10}\ m \tag{18.12}$$

The calculated $Rb-H$ is in good agreement with the experimental distance of $r_0(RbH) = 3.02\ X\ 10^{-10}\ m$ [2].

Using Eq. (18.3), the calculated lattice energy of CsH is:

$$\Delta U = 1.74756N\left(e3.89390\ eV\right) = 656.6\ kJ/mole = 156.9\ kcal/mole \tag{18.13}$$

This agrees well with the experimental lattice energy of $\Delta U = 154.46\ kcal/mole$ [1] and $\Delta U = 162.0\ kcal/mole$ [2] and confirms that the ionic compound CsH comprises a precise packing of discrete ions.

Substitution of $BE\left(Cs\right) = 6.23872\ X\ 10^{-19}\ J$ into Eq. (18.4) gives the $Cs — H$ distance $r_0\left(CsH\right)$:

$$r_0\left(CsH\right) = 3.24\ X\ 10^{-10}\ m \tag{18.14}$$

The calculated $Cs — H$ is in good agreement with the experimental distance of $r_0\left(CsH\right) = 3.19\ X\ 10^{-10}\ m$ [2].

POTASSIUM HYDRINO HYDRIDE ($KH\left(\frac{1}{4}\right)$)

The crystal structure of each alkali hydrino hydride $MH\left(\frac{1}{p}\right)$ is the same as that of the corresponding ordinary alkali hydride except that the radii of the hydride ions $H^-\left(\frac{1}{p}\right)$ are each a reciprocal integer times that of the ordinary hydride as given by Eq. (7.73). Thus, the lattice energy of $KH\left(\frac{1}{4}\right)$ is the same as that of KH given by Eq. (18.9), and the $K — H\left(\frac{1}{4}\right)$ distance $r_0\left(KH\left(\frac{1}{4}\right)\right)$ is the same as that of KH given by Eq. (18.10). Using the $K — H\left(\frac{1}{4}\right)$ distance (Eq. (18.10)), the radius of K^+ of $0.85215a_0$ (Eq. (10.399)) and the radius of $H^-\left(\frac{1}{4}\right)$ of $\frac{1.8660}{4}a_0 = 0.4665a_0$ (Eq. (7.73)), the lattice structure of $KH\left(\frac{1}{4}\right)$ is shown in Figure 18.1D.

ALKALI-HALIDE CRYSTAL STRUCTURES

The alkali halides (MX) are lithium, sodium, potassium, rubidium, and cesium cations, M^+, with fluoride, chloride, bromide, and iodide anions, X^-. These saline or salt-like alkali-metal halides each comprise an equal number of alkali cations and halide ions [3] in unit cells of a crystalline lattice. The crystal structure of these ionic compounds is the face-centered cubic $NaCl$ structure except for $CsCl$, $CsBr$, and CsI that have the $CsCl$ structure at ordinary temperatures and pressures [3]. These close-packed structures are expected since it gives the optimal approach of the positive and negative ions [3]. The $NaCl$ structure comprises face-centered cubes of both M^+ and X^- ions combined, but offset by half a unit cell length in one direction so that M^+ ions are centered in the edges of the X^- lattice and vice versa. Each M^+ is surrounded by six nearest neighbor X^- ions and vice versa. The resulting unit cell consists of anions (or cations) at the midpoint of each edge and at the center of the cell such that the unit cell contains four cations and four anions. The $CsCl$ structure comprises body-centered cubes of both M^+ and X^- ions wherein M^+ is in the center of cubes of X^- and vice versa.

ALKALI-HALIDE LATTICE PARAMETERS AND ENERGIES

The interionic radius of each alkali halide can be derived by considering the radii of the alkali ion and the halide ion, the electron energies at these radii, and the conditions for stability of the ions as the internuclear distance changes and the ions are mutually influenced by the Coulombic fields. Then, the lattice energy is given by the sum over the crystal of the minimum energy of the interacting ion pairs at the radius of minimum approach for which the ions are stable. The sum is further over all Coulombic interactions of the ions of the crystal.

As in the case with alkali hydrides, each alkali halide MX ($M = Li, Na, K, Rb, Cs$ and $X = F, Cl, Br, I$) is comprised of M^+ and X^- ions. From Coulomb's law, the lattice energy ΔU for point charges is given by Eq. (18.1), the Born-Mayer equation. The $M — X$ distance can be calculated from the minimum energy packing of the ions, which is stable. Each ion of the $NaCl$ and $CsCl$ structure is surrounded in a symmetrical octahedral or cubic field of six or four counterions, respectively. From Eq. (18.1), the lattice energy increases as the interionic distance decreases. But, the interionic distance cannot be the sum of the contact radii. This is easily appreciated by considering that the energies of the outer electron of M^+ and the outer electrons of X^- are very different. For sufficiently small interionic distances, the most energetic reaction that can occur which eliminates the cation and consequently the lattice energy is given by Eq. (18.2). For shorter distances, the spherically symmetrical ${}^1S_0$ state of the halide ion is distorted by M^+, and it is not stable in the ionic crystal when the $M — X$ distance is sufficiently small. To first order, this distance is given by the condition that the total Coulombic energy of attractive terms of X^- in the field of M^+ as well as the repulsive terms between like-charged ions is equal to the binding energy of M, $BE\left(M\right)$, for the cations of the crystal.

As in the case of the alkali hydrides, the lattice energies of alkali halides are determined by the binding energy of the corresponding metal atom. However, for each alkali halide an additional energy term arises corresponding to the effect of the electric field of the metal ion on the magnetic forces and energy of the halide ion. With the binding of the ions in both alkali hydrides and halides, the electric field lines of the metal ions end on those of the negative ions. But, each electron of the hydride ion occupies a symmetrically symmetrical s orbital, and the electrons collectively comprise a filled s shell only such that there is no dipole to interact with the external electric field of the positive ions. Whereas, the outer shell of the halide ions comprise p-orbital electrons having magnetic dipoles. These dipoles can interact with the external electric field having dipole components. Thus, the cation-anion separation in ionic compounds having electrons with magnetic dipole moments due to orbital angular momentum is dependent on the effect of the electric field on the magnetic forces of the anion.

Since the magnetic field is a relativistic effect of the electric field and the electron's charge, e, charge-to-mass ratio, $\frac{e}{m_e}$, angular momentum of $\hbar$, and the magnetic moment of μ_B are relativistically invariant, it is not surprising as shown in the Stark Effect section that the energy, E_{Stark}, of a one-electron atom in an electric field follows from that of a magnetic dipole in a magnetic field, Eqs. (2.68-2.69), with the magnetic dipole moment replaced by the electric dipole moment and the magnetic flux replaced by the electric field $\mathbf{E}_{applied}$. Thus, in alkali halides, the change in Coulombic lattice energy due to the Stark effect is given by the change in magnetic energy of the anion. The Stark-effect energy can be expressed in terms of the magnetic-dipole energy according to Eqs. (2.73-2.75):

$$E = \mu_B B \tag{18.15}$$

The corresponding force $\mathbf{F}_{Stark}$ on the outer nth electron of the anion is given by Eqs. (7.27-7.31).

$$\mathbf{F}_{Stark} = \frac{1}{Z}\frac{\hbar^2}{m_e r_n^3}\sqrt{s(s+1)}\mathbf{i}_r \tag{18.16}$$

From the radius change and the magnetic energy change, the Stark energy component $\Delta E(ionization;\ X^-)$ is calculated. Then, the lattice energy is given by the product of Avogadro's number, the Madelung constant which takes into account all inverse r_0 (point-like) Coulombic interactions of the crystal, and the sum of $BE(M)$, and $\Delta E(ionization;\ X^-)$:

$$\Delta U = NM_c\left(BE(M) + \Delta E(ionization;\ X^-)\right) \tag{18.17}$$

Thus, M_c is the factor of stability of forming the crystal from M^+ and X^- ions. The values for the *NaCl* and *CsCl* structures are $M_c = 1.74756$ and $M_c = 1.76267$ [3], respectively.

Since the Coulombic potential of the ions is equivalent to that of point charges with some higher order ion-ion-interaction repulsive terms, the $M - X$ distance $r_0(MX)$ given using Eq. (18.1), Eq. (18.3), $BE(M)$ and $\Delta E(ionization;\ X^-)$ is:

$$r_0(MX) = \frac{\dfrac{Z_+Z_-e^2}{\left(BE(M)+\Delta E(ionization;\ X^-)\right)4\pi\varepsilon_0} + \sqrt{\left(\dfrac{Z_+Z_-e^2}{\left(BE(M)+\Delta E(ionization;\ X^-)\right)4\pi\varepsilon_0}\right)^2 - \dfrac{4\rho Z_+Z_-e^2}{\left(BE(M)+\Delta E(ionization;\ X^-)\right)4\pi\varepsilon_0}}}{2} \tag{18.18}$$

wherein $\rho = 0.2\ X\ 10^{-10}\ m$ for alkali halides [5, 7]. The parameters of the gas-phase halide ions are derived next following the same procedure as that used to solve multielectron atoms.

RADIUS AND IONIZATION ENERGY OF THE OUTER ELECTRON OF THE FLUORIDE ION

The fluoride atom comprises a nine-electron atom having a central charge of $Z = 9$ times that of the proton. There are two indistinguishable spin-paired electrons in an atomic orbital with radii r_1 and r_2 both given by Eq. (7.35) (Eq. (10.51)), two indistinguishable spin-paired electrons in an atomic orbital with radii r_3 and r_4 both given by Eq. (10.62), and two sets of paired and an unpaired electron in an atomic orbital at r_9 given by Eq. (10.182). The next electron which binds to form the corresponding ten-electron fluoride ion is attracted by the net magnetic force between the pairing (electron 10) and unpaired (electron 9) to form three pairs of electrons of opposite spin in p_x, p_y, and p_z orbitals of an atomic orbital at the same radius r_{10}. The resulting electron configuration is $1s^2 2s^2 2p^6$, and the orbital arrangement is:

$$\begin{array}{c} \text{2p state} \\ \underline{\uparrow\downarrow}\ \ \underline{\uparrow\downarrow}\ \ \underline{\uparrow\downarrow} \\ 1 \quad 0 \quad -1 \end{array} \tag{18.19}$$

corresponding to the ground state $^1S_0$.

Unlike the case of the hydride ion comprising a filled s shell only, the outer shell of the fluoride ion comprises additional orbitals to the one filled by the electron which binds to form the negative ion. The forces are purely magnetic in order to maintain the boundary conditions of an equipotential minimum energy for electrons of the additional orbitals. Thus, the central Coulomb force acts on the outer electron to cause it to bind wherein this electric force on the outer-most electron due to the nucleus and the inner nine electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele} = \frac{(Z-9)e^2}{4\pi\varepsilon_0 r_{10}^2}\mathbf{i}_\mathbf{r} = 0 \tag{18.20}$$

for $r > r_9$ with $Z = 9$.

As in the case with the closed-shell s orbitals, the spin-pairing force $\mathbf{F}_{mag}$ between electron 9 and electron 10 given by Eq. (7.24) is:

$$\mathbf{F}_{mag} = \frac{1}{Z}\frac{\hbar^2}{m_e r_{10}^3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{18.21}$$

Due to the spin-pairing force the diamagnetic forces and paramagnetic forces are altered relative to those of the isoelectronic neon atom. The energy of the fluoride ion is minimized and the angular momentum is conserved with the pairing of electron ten to fill the 2 p_y orbital. Then, the orbital angular momentum of each set of the 2 p_x and p_z spin-paired electrons give rise to the diamagnetic force (Eq. (10.82)), $\mathbf{F}_{diamagnetic}$:

$$\mathbf{F}_{diamagnetic} = -\left(\frac{1}{3}+\frac{2}{3}\right)\frac{\hbar^2}{4m_e r_{10}^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} = -\frac{\hbar^2}{4m_e r_{10}^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{18.22}$$

From Eq. (10.84), $\mathbf{F}_{mag\ 2}$ due to spin and orbital angular momentum is:

$$\mathbf{F}_{mag\ 2} = \frac{1}{Z}\frac{4\hbar^2}{m_e r_{10}^2 r_3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \tag{18.23}$$

The outward centrifugal force on electron 10 is balanced by the electric force and the magnetic forces (on electron 10). The radius of the outer electron is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (18.20)), diamagnetic (Eq. (18.22)), and paramagnetic (Eqs. (18.21) and (18.23)) forces as follows:

$$\frac{m_e v_{10}^2}{r_{10}} = \frac{(Z-9)e^2}{4\pi\varepsilon_0 r_{10}^2} - \frac{\hbar^2}{4m_e r_{10}^2 r_3}\sqrt{s(s+1)} + \frac{4\hbar^2}{Zm_e r_{10}^2 r_3}\sqrt{s(s+1)} + \frac{\hbar^2}{Zm_e r_{10}^3}\sqrt{s(s+1)} \tag{18.24}$$

Substitution of $v_{10} = \frac{\hbar}{m_e r_{10}}$ (Eq. (1.35)), $Z = 9$, and $s = \frac{1}{2}$ into Eq. (18.24) gives:

$$\frac{\hbar^2}{m_e r_{10}^3} = -\frac{\hbar^2}{4m_e r_{10}^2 r_3}\sqrt{\frac{3}{4}} + \frac{4\hbar^2}{9m_e r_{10}^2 r_3}\sqrt{\frac{3}{4}} + \frac{\hbar^2}{9m_e r_{10}^3}\sqrt{\frac{3}{4}} \tag{18.25}$$

$$r_{10} = \frac{\frac{\hbar^2}{m_e}\left(1-\frac{\sqrt{\frac{3}{4}}}{9}\right)}{-\frac{\hbar^2}{4m_e r_3}\sqrt{\frac{3}{4}} + \frac{4\hbar^2}{9m_e r_3}\sqrt{\frac{3}{4}}} \tag{18.26}$$

$$r_{10} = \frac{a_0\left(1-\frac{\sqrt{\frac{3}{4}}}{9}\right)}{\left(\frac{4}{9}-\frac{1}{4}\right)\frac{\sqrt{\frac{3}{4}}}{r_3}},\ r_3 \textit{ in units of } a_0 \tag{18.27}$$

Substitution of $\frac{r_3}{a_0} = 0.51382$ (Eq. (10.62)) into Eq. (18.27) gives:

$$r_{10} = 2.75769 a_0 \tag{18.28}$$

The ionization energy of the fluoride ion is given by the magnetic energy of the outer electron calculated by integrating the sum of the diamagnetic (Eq. (18.22)) and paramagnetic (Eqs. (18.21) and (18.23)) forces from r_{10} to ∞:

$$E_{magwork} = -\int_{r_{10}}^{\infty} -\frac{\hbar^2}{4m_e r_{10}^2 r_3}\sqrt{\frac{3}{4}} + \frac{4\hbar^2}{Zm_e r_{10}^2 r_3}\sqrt{\frac{3}{4}} + \frac{\hbar^2}{Zm_e r_{10}^3}\sqrt{\frac{3}{4}}dr = \frac{\hbar^2\sqrt{\frac{3}{4}}}{m_e r_{10}}\left(\left(\frac{4}{Z}-\frac{1}{4}\right)\frac{1}{r_3}+\frac{1}{2Zr_{10}}\right) \quad (18.29)$$

Eq. (18.29) with $r_3 = 0.51382a_0$ (Eq. (10.62)), $r_{10} = 2.75769a_0$ (Eq. (18.28)), and $Z = 9$ gives:

$$E(ionization;\ F^-) = 3.40603\ eV \quad (18.30)$$

The experimental ionization energy of the fluoride ion is [8] :

$$E(ionization;\ F^-) = 3.4011895\ eV \quad (18.31)$$

RADIUS AND IONIZATION ENERGY OF THE OUTER ELECTRON OF THE CHLORIDE ION

The chlorine atom comprises a seventeen-electron atom having a central charge of $Z = 17$ times that of the proton. There are two indistinguishable spin-paired electrons in an atomic orbital with radii r_1 and r_2 both given by Eq. (7.35) (Eq. (10.51)), two indistinguishable spin-paired electrons in an atomic orbital with radii r_3 and r_4 both given by Eq. (10.62), three sets of paired electrons in an atomic orbital at r_{10} given by Eq. (10.212), two indistinguishable spin-paired electrons in an atomic orbital with radii r_{11} and r_{12} both given by Eq. (10.255), and two sets of paired and an unpaired electron in an atomic orbital with radius r_{17} given by Eq. (10.363). The next electron which binds to form the corresponding eighteen-electron chloride ion is attracted by the net magnetic force between the pairing (electron 18) and unpaired (electron 17) to form three pairs of electrons of opposite spin in p_x, p_y, and p_z orbitals of an atomic orbital at the same radius r_{18}. The resulting electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^6$, and the orbital arrangement is:

3p state

$$\underline{\uparrow\ \downarrow}\quad \underline{\uparrow\ \downarrow}\quad \underline{\uparrow\ \downarrow} \quad (18.32)$$

1 0 -1

corresponding to the ground state ${}^1S_0$.

Unlike the case of the hydride ion, the outer shell of the chloride ion comprises additional orbitals to the one filled by the electron which binds to form the negative ion. The forces are purely magnetic in order to maintain the boundary conditions of an equipotential minimum energy for electrons of the additional orbitals. Thus, the central Coulomb force acts on the outer electron to cause it to bind wherein this electric force on the outer-most electron due to the nucleus and the inner seventeen electrons is given by Eq. (10.70) with the appropriate charge and radius:

$$\mathbf{F}_{ele} = \frac{(Z-17)e^2}{4\pi\varepsilon_0 r_{18}^2}\mathbf{i}_\mathbf{r} = 0 \quad (18.33)$$

for $r > r_{17}$ with $Z = 17$.

As in the case with the closed-shell s orbitals, the spin-pairing force $\mathbf{F}_{mag}$ between electron 18 and electron 17 given by Eq. (7.24) is

$$\mathbf{F}_{mag} = \frac{1}{Z}\frac{\hbar^2}{m_e r_{18}^3}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \quad (18.34)$$

Due to the spin-pairing force the diamagnetic forces and paramagnetic forces are altered relative to those of the isoelectronic argon atom. The energy of the chloride ion is minimized and the angular momentum is conserved with the pairing of electron eighteen to fill the 3 p_y orbital when the orbital angular momentum of each set of the p_x, p_y, and p_z spin-paired electrons add negatively to cancel. Then, the diamagnetic force (Eq. (10.82)), $\mathbf{F}_{diamagnetic}$, is zero as in the case of the closed-p-shell atom neon:

$$\mathbf{F}_{diamagnetic} = 0 \quad (18.35)$$

The orbital angular momentum of each set of the 3 p_x and p_z spin-paired electrons and the spin and orbital angular momentum of electrons 17 and 18 that pair upon the binding to fill the 3 p_y shell give rise to the magnetic force $\mathbf{F}_{mag\ 2}$ with the corresponding contributions given by Eqs. (10.83) and (10.84), respectively:

$$\mathbf{F}_{mag\ 2} = (1+1)\frac{1}{Z}\frac{\hbar^2}{m_e r_{18}^2 r_{12}}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} + \frac{1}{Z}\frac{4\hbar^2}{m_e r_{18}^2 r_{12}}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} = \frac{1}{Z}\frac{6\hbar^2}{m_e r_{18}^2 r_{12}}\sqrt{s(s+1)}\mathbf{i}_\mathbf{r} \quad (18.36)$$

The outward centrifugal force on electron 18 is balanced by the electric force and the magnetic forces (on electron 18). The radius of the outer electron is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (18.33)), diamagnetic (Eq. (18.35)), and paramagnetic (Eqs. (18.34) and (18.36)) forces as follows:

$$\frac{m_e v_{18}^2}{r_{18}} = \frac{(Z-17)e^2}{4\pi\varepsilon_0 r_{18}^2} + \frac{6\hbar^2}{Zm_e r_{18}^2 r_{12}}\sqrt{s(s+1)} + \frac{\hbar^2}{Zm_e r_{18}^3}\sqrt{s(s+1)} \tag{18.37}$$

Substitution of $v_{18} = \frac{\hbar}{m_e r_{18}}$ (Eq. (1.35)), $Z = 17$, and $s = \frac{1}{2}$ into Eq. (18.37) gives:

$$\frac{\hbar^2}{m_e r_{18}^3} = \frac{6\hbar^2}{17m_e r_{18}^2 r_{12}}\sqrt{\frac{3}{4}} + \frac{\hbar^2}{17m_e r_{18}^3}\sqrt{\frac{3}{4}} \tag{18.38}$$

$$r_{18} = \frac{\frac{\hbar^2}{m_e}\left(1 - \frac{\sqrt{\frac{3}{4}}}{17}\right)}{\frac{6\hbar^2}{17m_e r_{12}}\sqrt{\frac{3}{4}}} \tag{18.39}$$

$$r_{18} = \frac{a_0\left(1 - \frac{\sqrt{\frac{3}{4}}}{17}\right)}{\frac{6\sqrt{\frac{3}{4}}}{17 r_{12}}},\ r_{12}\ \textit{in units of}\ a_0 \tag{18.40}$$

Substitution of $\frac{r_{12}}{a_0} = 0.86545$ (Eq. (10.255)) into Eq. (18.40) gives:

$$r_{18} = 2.68720 a_0 \tag{18.41}$$

The ionization energy of the chloride ion is given by the magnetic energy of the outer electron calculated by integrating the sum of the diamagnetic (Eq. (18.35)) and paramagnetic (Eqs. (18.34) and (18.36)) forces from r_{18} to ∞:

$$E_{magwork} = -\int_{r_{18}}^{\infty} \frac{6\hbar^2}{Zm_e r_{18}^2 r_{12}}\sqrt{\frac{3}{4}} + \frac{\hbar^2}{Zm_e r_{18}^3}\sqrt{\frac{3}{4}}dr = \frac{\hbar^2\sqrt{\frac{3}{4}}}{Zm_e r_{18}}\left(\frac{6}{r_{12}} + \frac{1}{2r_{18}}\right) \tag{18.42}$$

Eq. (18.42) with $r_{12} = 0.86545 a_0$ (Eq. (10.255)), $r_{18} = 2.68720 a_0$ (Eq. (18.41)), and $Z = 17$ gives:

$$E(\textit{ionization};\ Cl^-) = 3.67238\ eV \tag{18.43}$$

The experimental ionization energy of the chloride ion is [8]:

$$E(\textit{ionization};\ Cl^-) = 3.612724\ eV \tag{18.44}$$

CHANGE IN THE RADIUS AND IONIZATION ENERGY OF THE FLUORIDE ION DUE TO THE ION FIELD

As in the case of the alkali hydrides, the lattice energies of alkali halides are equivalent to the binding energy of the corresponding metal atom, except for an additional energy term corresponding to the Stark effect of the metal ion on the magnetic forces and energy of the halide ion. The corresponding force $\mathbf{F}_{Stark}$ on the outer electron of the fluoride ion given by Eq. (18.16) is

$$\mathbf{F}_{Stark} = \frac{1}{Z}\frac{\hbar^2}{m_e r_{10}^3}\sqrt{s(s+1)}\mathbf{i}_r \tag{18.45}$$

Then, the outward centrifugal force on electron 10 is balanced by the electric force and the magnetic forces (on electron 10). The radius of the outer electron is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (18.20)), diamagnetic (Eq. (18.22)), and paramagnetic (Eqs. (18.21), (18.23), and (18.45)) forces as follows:

$$\frac{m_e v_{10}^2}{r_{10}} = \frac{(Z-9)e^2}{4\pi\varepsilon_0 r_{10}^2} - \frac{\hbar^2}{4m_e r_{10}^2 r_3}\sqrt{s(s+1)} + \frac{4\hbar^2}{Zm_e r_{10}^2 r_3}\sqrt{s(s+1)} + \frac{2\hbar^2}{Zm_e r_{10}^3}\sqrt{s(s+1)} \tag{18.46}$$

Substitution of $v_{10} = \frac{\hbar}{m_e r_{10}}$ (Eq. (1.35)), $Z = 9$, and $s = \frac{1}{2}$ into Eq. (18.46) gives:

$$r_{10} = \frac{a_0\left(1 - \frac{2\sqrt{\frac{3}{4}}}{9}\right)}{\left(\frac{4}{9} - \frac{1}{4}\right)\frac{\sqrt{\frac{3}{4}}}{r_3}},\ r_3\ \textit{in units of}\ a_0 \tag{18.47}$$

Substitution of $\frac{r_3}{a_0} = 0.51382$ (Eq. (10.62)) into Eq. (18.47) gives:

$$r_{10} = 2.46408 a_0 \tag{18.48}$$

The ionization energy of the fluoride ion is given by the magnetic energy of the outer electron calculated by integrating the sum of the diamagnetic (Eq. (18.22)) and paramagnetic (Eqs. (18.21), (18.23), and (18.45)) forces from r_{10} to ∞:

$$E_{magwork} = -\int_{r_{10}}^{\infty} -\frac{\hbar^2}{4m_e r_{10}^2 r_3}\sqrt{\frac{3}{4}} + \frac{4\hbar^2}{Zm_e r_{10}^2 r_3}\sqrt{\frac{3}{4}} + \frac{2\hbar^2}{Zm_e r_{10}^3}\sqrt{\frac{3}{4}} dr = \frac{\hbar^2\sqrt{\frac{3}{4}}}{m_e r_{10}}\left(\left(\frac{4}{Z} - \frac{1}{4}\right)\frac{1}{r_3} + \frac{1}{Zr_{10}}\right) \tag{18.49}$$

Eq. (18.49) with $r_3 = 0.51382 a_0$ (Eq. (10.62)), $r_{10} = 2.46408 a_0$ (Eq. (18.48)), and $Z = 9$ gives:

$$E(ionization;\ F^-) = 4.05046\ eV \tag{18.50}$$

The energy change of the fluoride ion $\Delta E(ionization;\ F^-)$ due to the Stark effect is given by the difference between Eqs. (18.50) and (18.30):

$$\Delta E(ionization;\ F^-) = 4.05046\ eV - 3.40603\ eV = 0.64444\ eV \tag{18.51}$$

CHANGE IN THE RADIUS AND IONIZATION ENERGY OF THE CHLORIDE ION DUE TO THE ION FIELD

Similar to the case of the alkali fluorides, the lattice energies of alkali chlorides are equivalent to the binding energy of the corresponding metal atom, except for those cases where there is an additional energy term corresponding to the Stark effect of the metal ion on the magnetic forces and energy of the chloride ion. The selection rules for the Stark effect in one-electron atoms given by Eq. (2.78) is:

$$\begin{aligned} &n = 1,2,3,4,... \\ &\ell = n-1 \\ &m_\ell = -\ell, -\ell+1, ..., 0, ..., +\ell \\ &m_s = \pm\frac{1}{2} \end{aligned} \tag{18.52}$$

The corresponding energies are given in Table 2.3. For fluoride having an outer 2p shell:

$$m_\ell = 1 \tag{18.53}$$

corresponding to the force $\mathbf{F}_{Stark}$ on the outer electron of the fluoride ion given by Eq. (18.45) and the binding energy change $\Delta E(ionization;\ F^-)$ given by Eq. (18.50).

In the case of the chloride ion, the outer shell is $3p$. For cations having an outer filled *ns or np*; $n < 3$ shell, the interaction of the $3p$ and $2p$ shells of Cl^- due to the field of the cation gives rise to a diamagnetic Stark force $\mathbf{F}_{Stark}$ corresponding to the selection rule:

$$m_\ell = -1 \tag{18.54}$$

wherein the cation's electrons cannot compensate for the diamagnetism by changing orientation. Thus, for Li^+ and Na^+

$$\mathbf{F}_{Stark} = -\frac{1}{Z}\frac{\hbar^2}{m_e r_{18}^3}\sqrt{s(s+1)}\mathbf{i}_r \tag{18.55}$$

and for K^+, Rb^+, and Cs^+ with *ns or np*; $n \geq 3$

$$\mathbf{F}_{Stark} = 0 \tag{18.56}$$

Then, the outward centrifugal force on electron 18 is balanced by the electric force and the magnetic forces (on electron 18). The radius of the outer electron is calculated by equating the outward centrifugal force to the sum of the electric (Eq. (18.33)), diamagnetic (Eq. (18.35)), and paramagnetic (Eqs. (18.34), (18.36), and (18.55)) forces as follows:

$$\frac{m_e v_{18}^2}{r_{18}} = \frac{(Z-17)e^2}{4\pi\varepsilon_0 r_{18}^2} + \frac{6\hbar^2}{Zm_e r_{18}^2 r_{12}}\sqrt{s(s+1)} \tag{18.57}$$

Substitution of $v_{18} = \frac{\hbar}{m_e r_{18}}$ (Eq. (1.35)), $Z = 17$, and $s = \frac{1}{2}$ into Eq. (18.57) gives:

$$r_{18} = \frac{a_0}{\frac{6\sqrt{\frac{3}{4}}}{17 r_{12}}},\ r_{12}\ in\ units\ of\ a_0 \tag{18.58}$$

Substitution of $\frac{r_{12}}{a_0} = 0.86545$ (Eq. (10.255)) into Eq. (18.58) gives:

$$r_{18} = 2.83145 a_0 \tag{18.59}$$

The ionization energy of the chloride ion is given by the magnetic energy of the outer electron calculated by integrating the sum of the diamagnetic (Eq. (18.35)) and paramagnetic (Eqs. (18.34), (18.36), and (18.55)) forces from r_{18} to ∞:

$$E_{magwork} = -\int_{r_{18}}^{\infty} \frac{6\hbar^2}{Z m_e r_{18}^2 r_{12}} \sqrt{\frac{3}{4}} dr = \frac{6\hbar^2 \sqrt{\frac{3}{4}}}{Z m_e r_{18} r_{12}} \tag{18.60}$$

Eq. (18.60) with $r_{12} = 0.86545 a_0$ (Eq. (10.255)), $r_{18} = 2.83145 a_0$ (Eq. (18.59)), and $Z = 17$ gives:

$$E(ionization;\ Cl^-) = 3.39420\ eV \tag{18.61}$$

For Li^+ and Na^+ chlorides, the energy change of the chloride ion $\Delta E(ionization;\ Cl^-)$ due to the Stark effect is given by the difference between Eqs. (18.61) and (18.43).

$$\Delta E(ionization;\ Cl^-) = 3.39420\ eV - 3.67238\ eV = -0.27818\ eV \tag{18.62}$$

LITHIUM FLUORIDE

The calculated ionic radii for Li^+ and F^- ions in LiF given by Eqs. (10.49) and (18.48) are $0.35566 a_0$ and $2.46408 a_0$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of Li^+ (Eqs. (7.35), (7.45-7.46), and (7.63)) and F^- (Eq. (18.50)) are $75.665\ eV$ and $4.05046\ eV$, respectively. Furthermore, since the calculated ionization energy (Eq. (10.25)) of Li to Li^+ is $5.40381\ eV$ as shown in Table 10.1 and the ionization energy (Eq. (18.50)) of F^- to F is $4.05046\ eV$, for sufficiently small interionic distances, the lithium ion may be reduced.

Substitution of $BE(Li) = 8.65786\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ F^-) = 0.64444\ eV\ \left(1.03251\ X\ 10^{-19}\ J\right)$ (Eq. (18.51)) into Eq. (18.17) gives the calculated lattice energy of:

$$\begin{aligned} \Delta U &= N M_c \left(BE(Li) + \Delta E(ionization;\ F^-) \right) \\ &= 1.74756 N \left(8.65786\ X\ 10^{-19}\ J + 1.03251\ X\ 10^{-19}\ J \right) \\ &= 1019.8\ kJ/mole\ \left(243.7\ kcal/mole\right) \end{aligned} \tag{18.63}$$

This agrees well with the experimental lattice energy of $\Delta U = 250.7\ kcal/mole$ [9] and confirms that the ionic compound LiF comprises a precise packing of discrete ions.

The $Li — F$ distance, $r_0(LiF)$, calculated using Eq. (18.18) with the substitution of $BE(Li) = 8.65786\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ F^-) = 1.03251\ X\ 10^{-19}\ J$ is:

$$r_0(LiF) = 2.16\ X\ 10^{-10}\ m \tag{18.64}$$

The calculated $Li — F$ is in reasonable agreement with the experimental distance of $r_0(LiF) = 2.01\ X\ 10^{-10}\ m$ [10]. Using the $Li — F$ distance and the calculated ionic radii, the lattice structure of LiF is shown in Figure 18.3A.

SODIUM FLUORIDE

The calculated ionic radii for Na^+ and F^- ions in NaF given by Eqs. (10.212) and (18.48) are $0.560945 a_0$ and $2.46408 a_0$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of Na^+ (Eqs. (10.212-10.213)) and F^- (Eq. (18.50)) are $48.5103\ eV$ and $4.05046\ eV$, respectively. Furthermore, since the calculated ionization energy (Eqs. (10.226-10.227)) of Na to Na^+ is $5.12592\ eV$ as shown in Table 10.10 and the ionization energy (Eq. (18.50)) of F^- to F is $4.05046\ eV$, for sufficiently small interionic distances, the sodium ion may be reduced.

Substitution of $BE(Na) = 8.21263\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ F^-) = 1.03251\ X\ 10^{-19}\ J$ (Eq. (18.51)) into Eq. (18.17) gives the calculated lattice energy of:

$$\begin{aligned} \Delta U &= N M_c \left(BE(Na) + \Delta E(ionization;\ F^-) \right) \\ &= 1.74756 N \left(8.21263\ X\ 10^{-19}\ J + 1.03251\ X\ 10^{-19}\ J \right) \\ &= 972.95\ kJ/mole\ \left(232.54\ kcal/mole\right) \end{aligned} \tag{18.65}$$

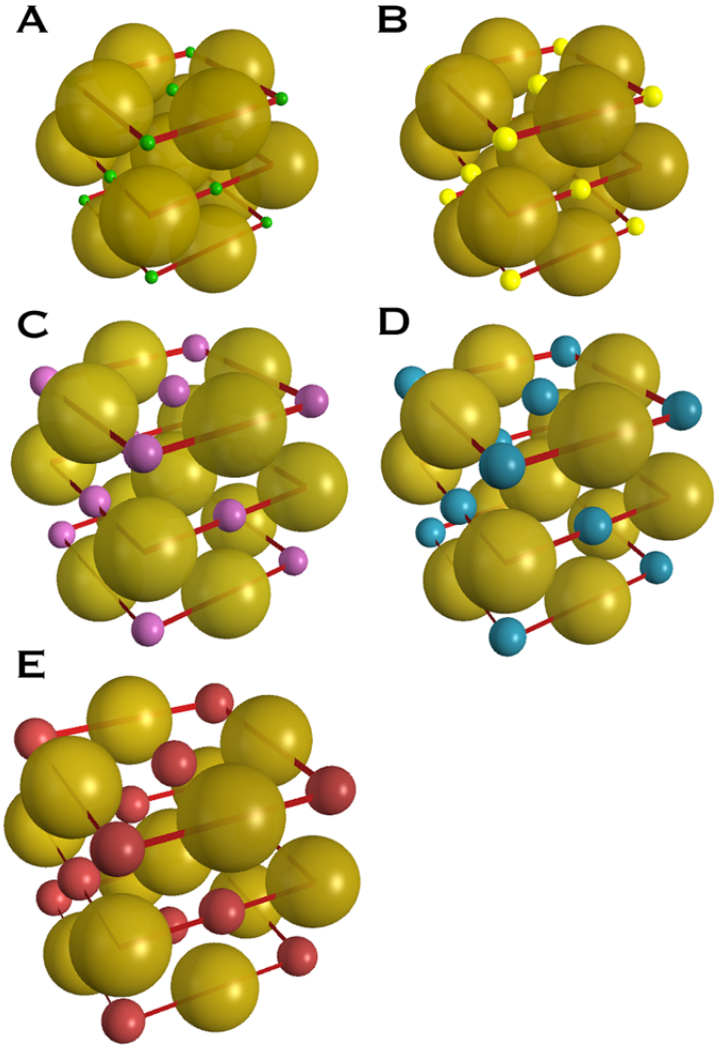
This agrees well with the experimental lattice energy of $\Delta U = 222\ kcal/mole$ [9] and confirms that the ionic compound NaF comprises a precise packing of discrete ions.

The $Na — F$ distance, $r_0(NaF)$, calculated using Eq. (18.18) with the substitution of $BE(Na) = 8.21263\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ F^-) = 1.03251\ X\ 10^{-19}\ J$ is:

$$r_0(NaF) = 2.28\ X\ 10^{-10}\ m \tag{18.66}$$

The calculated $Na — F$ is in reasonable agreement with the experimental distance of $r_0(NaF) = 2.32\ X\ 10^{-10}\ m$ [10]. Using the $Na — F$ distance and the calculated ionic radii, the lattice structure of NaF is shown in Figure 18.3B.

Figure 18.3. The crystal structures of MF all to the same scale. (Li^+ = green, Na^+ = yellow, K^+ = purple, Rb^+ = blue, Cs^+ = red, and F^- = gold). (A) The crystal structure of LiF. (B) The crystal structure of NaF. (C) The crystal structure of KF. (D) The crystal structure of RbF. (E) The crystal structure of CsF.



POTASSIUM FLUORIDE

The calculated ionic radii for K^+ and F^- ions in KF given by Eqs. (10.399) and (18.48) are $0.85215a_0$ and $2.46408a_0$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of K^+ (Eqs. (10.399-10.400)) and F^- (Eq. (18.50)) are 31.9330 eV and 4.05046 eV, respectively. Furthermore, since the calculated ionization energy (Eqs. (10.414-10.415)) of K to K^+ is 4.33 eV as shown in Table 10.19 and the ionization energy (Eq. (18.50)) of F^- to F is 4.05046 eV, for sufficiently small interionic distances, the potassium ion may be reduced.

Substitution of $BE(K) = 6.93095\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ F^-) = 1.03251\ X\ 10^{-19}\ J$ (Eq. (18.51)) into Eq. (18.17) gives the calculated lattice energy of:

$$\begin{aligned} \Delta U &= NM_c\left(BE(K) + \Delta E(ionization;\ F^-)\right) \\ &= 1.74756N\left(6.93095\ X\ 10^{-19}\ J + 1.03251\ X\ 10^{-19}\ J\right) \\ &= 838.06\ kJ/mole\ \left(200.30\ kcal/mole\right) \end{aligned} \tag{18.67}$$

This agrees well with the experimental lattice energy of $\Delta U = 198\ kcal/mole$ [9] and confirms that the ionic compound KF comprises a precise packing of discrete ions.

The $K — F$ distance, $r_0(KF)$, calculated using Eq. (18.18) with the substitution of $BE(K) = 6.93095\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ F^-) = 1.03251\ X\ 10^{-19}\ J$ is:

$$r_0(KF) = 2.68\ X\ 10^{-10}\ m \tag{18.68}$$

The calculated $K — F$ is in reasonable agreement with the experimental distance of $r_0(KF) = 2.67\ X\ 10^{-10}\ m$ [10]. Using the $K — F$ distance and the calculated ionic radii, the lattice structure of KF is shown in Figure 18.3C.

RUBIDIUM FLUORIDE

The Rb^+ ionic radius calculated using Eq. (10.102) and the experimental ionization energy of Rb^+, $27.2895\ eV$ [6] is $0.99714a_0$ and the calculated ionic radius F^- ions in RbF given by Eq. (18.48) is $2.46408a_0$. But, the interionic distance cannot be the sum of the contact radii since the experimental and calculated ionization energies of Rb^+ [6] and F^- (Eq. (18.50)) are $27.2895\ eV$ and $4.05046\ eV$, respectively. Furthermore, since the experimental ionization energy of Rb to Rb^+ is $4.177128\ eV$ [6] and the ionization energy (Eq. (18.50)) of F^- to F is $4.05046\ eV$, for sufficiently small interionic distances, the rubidium ion may be reduced.

Substitution of $BE(Rb) = 6.6925\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ F^-) = 1.03251\ X\ 10^{-19}\ J$ (Eq. (18.51)) into Eq. (18.17) gives the calculated lattice energy of:

$$\begin{aligned}\Delta U &= NM_c\left(BE(Rb) + \Delta E(ionization;\ F^-)\right)\\ &= 1.74756N\left(6.6925\ X\ 10^{-19}\ J + 1.03251\ X\ 10^{-19}\ J\right)\\ &= 812.97\ kJ/mole\ \ (194.30\ kcal/mole)\end{aligned} \tag{18.69}$$

This agrees well with the experimental lattice energy of $\Delta U = 190\ kcal/mole$ [9] and confirms that the ionic compound RbF comprises a precise packing of discrete ions.

The $Rb — F$ distance, $r_0(RbF)$, calculated using Eq. (18.18) with the substitution of $BE(Rb) = 6.6925\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ F^-) = 1.03251\ X\ 10^{-19}\ J$ is:

$$r_0(RbF) = 2.77\ X\ 10^{-10}\ m \tag{18.70}$$

The calculated $Rb — F$ is in reasonable agreement with the experimental distance of $r_0(RbF) = 2.83\ X\ 10^{-10}\ m$ [10]. Using the $Rb — F$ distance and the ionic radii, the lattice structure of RbF is shown in Figure 18.3D.

CESIUM FLUORIDE

The Cs^+ ionic radius calculated using Eq. (10.102) and the experimental ionization energy of Cs^+, $23.15744\ eV$ [6] is $1.17506a_0$ and the calculated ionic radius F^- ions in CsF given by Eq. (18.48) is $2.46408a_0$. But, the interionic distance cannot be the sum of the contact radii since the experimental and calculated ionization energies of Cs^+ [6] and F^- (Eq. (18.50)) are $23.15744\ eV$ and $4.05046\ eV$, respectively. Furthermore, since the experimental ionization energy of Cs to Cs^+ is $3.893905\ eV$ [6] and the ionization energy (Eq. (18.50)) of F^- to F is $4.05046\ eV$, for sufficiently small interionic distances, the cesium ion may be reduced.

Substitution of $BE(Cs) = 6.23872\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ F^-) = 1.03251\ X\ 10^{-19}\ J$ (Eq. (18.51)) into Eq. (18.17) gives the calculated lattice energy of:

$$\begin{aligned}\Delta U &= NM_c\left(BE(Cs) + \Delta E(ionization;\ F^-)\right)\\ &= 1.74756N\left(6.23872\ X\ 10^{-19}\ J + 1.03251\ X\ 10^{-19}\ J\right)\\ &= 765.21\ kJ/mole\ \ (182.89\ kcal/mole)\end{aligned} \tag{18.71}$$

This agrees well with the experimental lattice energy of $\Delta U = 181\ kcal/mole$ [9] and confirms that the ionic compound CsF comprises a precise packing of discrete ions.

The $Cs — F$ distance, $r_0(CsF)$, calculated using Eq. (18.18) with the substitution of $BE(Cs) = 6.23872\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ F^-) = 1.03251\ X\ 10^{-19}\ J$ is:

$$r_0(CsF) = 2.96\ X\ 10^{-10}\ m \tag{18.72}$$

The calculated $Cs — F$ is in reasonable agreement with the experimental distance of $r_0(CsF) = 3.01\ X\ 10^{-10}\ m$ [10]. Using the $Cs — F$ distance and the ionic radii, the lattice structure of CsF is shown in Figure 18.3E.

LITHIUM CHLORIDE

The calculated ionic radii for Li^+ and Cl^- ions in $LiCl$ given by Eqs. (10.49) and (18.59) are $0.35566a_0$ and $2.83145a_0$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of Li^+ (Eqs. (7.35), (7.45-7.46), and (7.63)) and Cl^- (Eq. (18.61)) are $75.665\ eV$ and $3.39420\ eV$, respectively. Furthermore, since the calculated ionization energy (Eq. (10.25)) of Li to Li^+ is $5.40381\ eV$ as shown in Table 10.1 and the ionization energy (Eq. (18.61)) of Cl^- to Cl is $3.39420\ eV$, for sufficiently small interionic distances, the lithium ion may be reduced.

Substitution of $BE\left(Li\right)=8.65786\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ Cl^-)=-0.27818\ eV\ \left(-4.45691\ X\ 10^{-20}\ J\right)$ (Eq. (18.62)) into Eq. (18.17) gives the calculated lattice energy of:

$$\begin{aligned}\Delta U &= NM_c\left(BE\left(Li\right)+\Delta E(ionization;\ Cl^-)\right)\\ &=1.74756N\left(8.65786\ X\ 10^{-19}\ J-4.45691\ X\ 10^{-20}\ J\right)\\ &=864.24\ kJ/mole\ \left(206.56\ kcal/mole\right)\end{aligned}\tag{18.73}$$

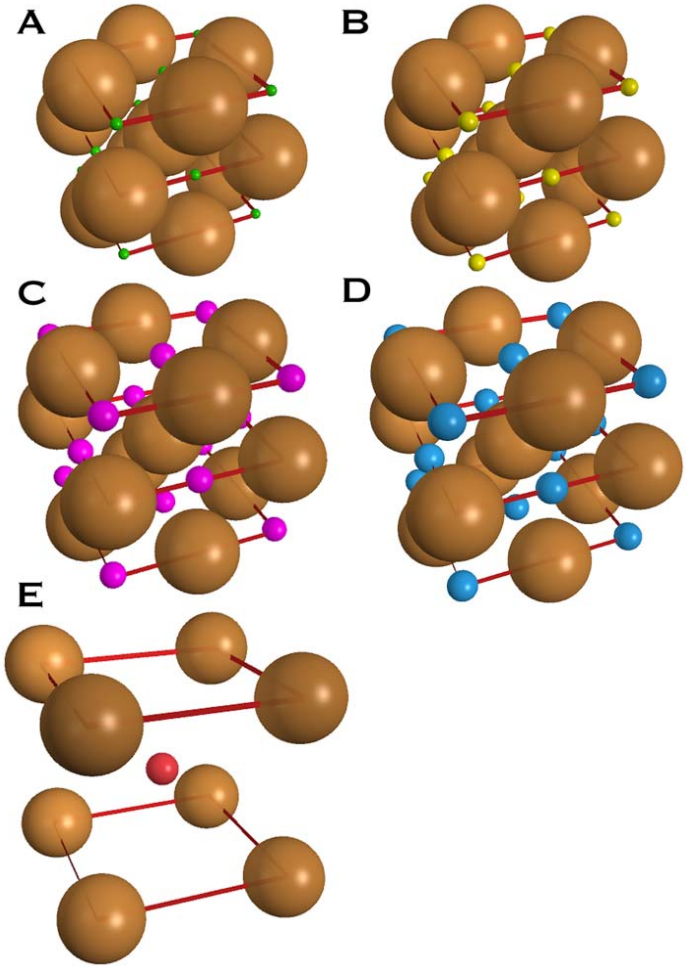
This agrees well with the experimental lattice energy of $\Delta U=207\ kcal/mole$ [9] and confirms that the ionic compound $LiCl$ comprises a precise packing of discrete ions.

The $Li\text{—}Cl$ distance, $r_0\left(LiCl\right)$, calculated using Eq. (18.18) with the substitution of $BE\left(Li\right)=8.65786\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ Cl^-)=-4.45691\ X\ 10^{-20}\ J$ is:

$$r_0\left(LiCl\right)=2.59\ X\ 10^{-10}\ m\tag{18.74}$$

The calculated $Li\text{—}Cl$ is in reasonable agreement with the experimental distance of $r_0\left(LiCl\right)=2.57\ X\ 10^{-10}\ m$ [10]. Using the $Li\text{—}Cl$ distance and the calculated ionic radii, the lattice structure of $LiCl$ is shown in Figure 18.4A.

Figure 18.4. The crystal structures of MCl all to the same scale. (Li^+ = green, Na^+ = yellow, K^+ = purple, Rb^+ = blue, Cs^+ = red, and Cl^- = brown). (A) The crystal structure of $LiCl$. (B) The crystal structure of $NaCl$. (C) The crystal structure of KCl. (D) The crystal structure of $RbCl$. (E) The crystal structure of $CsCl$.



SODIUM CHLORIDE

The calculated ionic radii for Na^+ and Cl^- ions in $NaCl$ given by Eqs. (10.212) and (18.59) are $0.560945a_0$ and $2.83145a_0$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of Na^+ (Eqs. (10.212-10.213)) and Cl^- (Eq. (18.61)) are $48.5103\ eV$ and $3.39420\ eV$, respectively. Furthermore, since the calculated ionization energy (Eqs. (10.226-10.227)) of Na to Na^+ is $5.12592\ eV$ as shown in Table 10.10 and the ionization energy (Eq. (18.61)) of Cl^- to Cl is $3.39420\ eV$, for sufficiently small interionic distances, the sodium ion may be reduced.

Substitution of $BE(Na) = 8.21263\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ Cl^-) = -4.45691\ X\ 10^{-20}\ J$ (Eq. (18.62)) into Eq. (18.17) gives the calculated lattice energy of:

$$\begin{aligned} \Delta U &= NM_c\left(BE(Na) + \Delta E(ionization;\ Cl^-)\right) \\ &= 1.74756N\left(8.21263\ X\ 10^{-19}\ J - 4.45691\ X\ 10^{-20}\ J\right) \\ &= 817.38\ kJ/mole\ \ (195.36\ kcal/mole) \end{aligned} \tag{18.75}$$

This agrees well with the experimental lattice energy of $\Delta U = 189\ kcal/mole$ [9] and confirms that the ionic compound $NaCl$ comprises a precise packing of discrete ions.

The $Na-Cl$ distance, $r_0(NaCl)$, calculated using Eq. (18.18) with the substitution of $BE(Na) = 8.21263\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ Cl^-) = -4.45691\ X\ 10^{-20}\ J$ is:

$$r_0(NaCl) = 2.75\ X\ 10^{-10}\ m \tag{18.76}$$

The calculated $Na-Cl$ is in reasonable agreement with the experimental distance of $r_0(NaCl) = 2.82\ X\ 10^{-10}\ m$ [10]. Using the $Na-Cl$ distance and the calculated ionic radii, the lattice structure of $NaCl$ is shown in Figure 18.4B.

POTASSIUM CHLORIDE

The calculated ionic radii for K^+ and Cl^- ions in KCl given by Eqs. (10.399) and (18.59) are $0.85215a_0$ and $2.83145a_0$, respectively. But, the interionic distance cannot be the sum of the contact radii since the calculated ionization energies of K^+ (Eqs. (10.399-10.400)) and Cl^- (Eq. (18.61)) are $31.9330\ eV$ and $3.39420\ eV$, respectively. Furthermore, since the calculated ionization energy (Eqs. (10.414-10.415)) of K to K^+ is $4.33\ eV$ as shown in Table 10.19 and the ionization energy (Eq. (18.61)) of Cl^- to Cl is $3.39420\ eV$, for sufficiently small interionic distances, the potassium ion may be reduced.

Substitution of $BE(K) = 6.93095\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ Cl^-) = -4.45691\ X\ 10^{-20}\ J$ (Eq. (18.62)) into Eq. (18.17) gives the calculated lattice energy of:

$$\begin{aligned} \Delta U &= NM_c\left(BE(K) + \Delta E(ionization;\ Cl^-)\right) \\ &= 1.74756N\left(6.93095\ X\ 10^{-19}\ J - 4.45691\ X\ 10^{-20}\ J\right) \\ &= 729.41\ kJ/mole\ \ (174.33\ kcal/mole) \end{aligned} \tag{18.77}$$

This agrees well with the experimental lattice energy of $\Delta U = 172\ kcal/mole$ [9] and confirms that the ionic compound KCl comprises a precise packing of discrete ions.

The $K-Cl$ distance, $r_0(KCl)$, calculated using Eq. (18.18) with the substitution of $BE(K) = 6.93095\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ Cl^-) = -4.45691\ X\ 10^{-20}\ J$ is:

$$r_0(KCl) = 3.11\ X\ 10^{-10}\ m \tag{18.78}$$

The calculated $K-Cl$ is in reasonable agreement with the experimental distance of $r_0(KCl) = 3.15\ X\ 10^{-10}\ m$ [10]. Using the $K-Cl$ distance and the calculated ionic radii, the lattice structure of KCl is shown in Figure 18.4C.

RUBIDIUM CHLORIDE

The Rb^+ ionic radius calculated using Eq. (10.102) and the experimental ionization energy of Rb^+, $27.2895\ eV$ [6] is $0.99714a_0$ and the calculated ionic radius Cl^- ions in $RbCl$ given by Eq. (18.59) is $2.83145a_0$. But, the interionic distance cannot be the sum of the contact radii since the experimental and calculated ionization energies of Rb^+ [6] and Cl^- (Eq. (18.61)) are $27.2895\ eV$ and $3.39420\ eV$, respectively. Furthermore, since the experimental ionization energy of Rb to Rb^+ is $4.177128\ eV$ [6] and the ionization energy (Eq. (18.61)) of Cl^- to Cl is $3.39420\ eV$, for sufficiently small interionic distances, the rubidium ion may be reduced.

Substitution of $BE(Rb) = 6.6925\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ Cl^-) = -4.45691\ X\ 10^{-20}\ J$ (Eq. (18.62)) into Eq. (18.17) gives the calculated lattice energy of:

$$\begin{aligned}\Delta U &= NM_c\left(BE\left(Rb\right)+\Delta E(ionization;\ Cl^-)\right)\\ &=1.74756N\left(6.6925\ X\ 10^{-19}\ J-4.45691\ X\ 10^{-20}\ J\right)\\ &=704.31\ kJ/mole\ \left(168.33\ kcal/mole\right)\end{aligned}\tag{18.79}$$

This agrees well with the experimental lattice energy of $\Delta U = 166\ kcal/mole$ [9] and confirms that the ionic compound $RbCl$ comprises a precise packing of discrete ions.

The $Rb\text{—}Cl$ distance, $r_0\left(RbCl\right)$, calculated using Eq. (18.18) with the substitution of $BE\left(Rb\right)=6.6925\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ Cl^-)=-4.45691\ X\ 10^{-20}\ J$ is:

$$r_0\left(RbCl\right)=3.23\ X\ 10^{-10}\ m\tag{18.80}$$

The calculated $Rb\text{—}Cl$ is in reasonable agreement with the experimental distance of $r_0\left(RbCl\right)=3.29\ X\ 10^{-10}\ m$ [10]. Using the $Rb\text{—}Cl$ distance and the ionic radii, the lattice structure of $RbCl$ is shown in Figure 18.4D.

CESIUM CHLORIDE

The Cs^+ ionic radius calculated using Eq. (10.102) and the experimental ionization energy of Cs^+, $23.15744\ eV$ [6] is $1.17506a_0$ and the calculated ionic radius Cl^- ions in $CsCl$ given by Eq. (18.59) is $2.83145a_0$. But, the interionic distance cannot be the sum of the contact radii since the experimental and calculated ionization energies of Cs^+ [6] and Cl^- (Eq. (18.61)) are $23.15744\ eV$ and $3.39420\ eV$, respectively. Furthermore, since the experimental ionization energy of Cs to Cs^+ is $3.893905\ eV$ [6] and the ionization energy (Eq. (18.61)) of Cl^- to Cl is $3.39420\ eV$, for sufficiently small interionic distances, the cesium ion may be reduced.

Substitution of $BE\left(Cs\right)=6.23872\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ Cl^-)=-4.45691\ X\ 10^{-20}\ J$ (Eq. (18.62)) into Eq. (18.17) gives the calculated lattice energy of:

$$\begin{aligned}\Delta U &= NM_c\left(BE\left(Cs\right)+\Delta E(ionization;\ Cl^-)\right)\\ &=1.76267N\left(6.23872\ X\ 10^{-19}\ J-4.45691\ X\ 10^{-20}\ J\right)\\ &=662.23\ kJ/mole\ \left(158.28\ kcal/mole\right)\end{aligned}\tag{18.81}$$

This agrees well with the experimental lattice energy of $\Delta U = 160\ kcal/mole$ [9] and confirms that the ionic compound $CsCl$ comprises a precise packing of discrete ions.

The $Cs\text{—}Cl$ distance, $r_0\left(CsCl\right)$, calculated using Eq. (18.18) with the substitution of $BE\left(Cs\right)=6.23872\ X\ 10^{-19}\ J$ and $\Delta E(ionization;\ Cl^-)=-4.45691\ X\ 10^{-20}\ J$ is:

$$r_0\left(CsCl\right)=3.49\ X\ 10^{-10}\ m\tag{18.82}$$

The calculated $Cs\text{—}Cl$ is in reasonable agreement with the experimental distance of $r_0\left(CsCl\right)=3.54\ X\ 10^{-10}\ m$ [10]. Using the $Cs\text{—}Cl$ distance and the ionic radii, the lattice structure of $CsCl$ is shown in Figure 18.4E.

Chapter 19

THE NATURE OF THE METALLIC BOND OF ALKALI METALS

GENERALIZATION OF THE NATURE OF THE METALLIC BOND

Common metals comprise alkali, alkaline earth, and transition elements and have the properties of high electrical and thermal conductivity, opacity, surface luster, ductility, and malleability. From Maxwell's equations, the electric field inside of a metal conductor is zero. As shown in Appendix II, the bound electron exhibits this feature. The charge is confined to a two-dimensional layer and the field is normal and discontinuous at the surface. The relationship between the electric field equation and the electron source charge-density function is given by Maxwell's equation in two dimensions [1-3].

$$\mathbf{n} \bullet \left(\mathbf{E}_1 - \mathbf{E}_2 \right) = \frac{\sigma}{\varepsilon_0} \tag{19.1}$$
