December 19, 2023

# Catalytic Reaction of Atomic Hydrogen to Hydrino®

1. Atomic hydrogen reacts with an energy acceptor called a catalyst wherein energy is transferred from atomic hydrogen to the catalyst which forms an ion due to accepting the energy
2. Then, the negative electron drops to a lower shell closer to the positive proton to form a smaller hydrogen atom called a "hydrino" releasing energy that ultimately is in the form of heat
3. The catalyst ion regains its lost electrons to reform the catalyst for another cycle with the release of the initial energy accepted from hydrogen. With the imposition of an arc current condition, the limiting space charge of the ionized electrons is eliminated and the rate becomes massively high.

# Hydrino transition EUV continuum results offer resolution to many otherwise inexplicable celestial observations with

- (a) the energy and radiation from the hydrino transitions being the cause of sunspots and other solar activity, why the Sun emits X-rays, the missing energy balance, the source of extraordinary temperatures and power regarding the solar corona problem wherein the highly ionized ions are from EUV continuum radiation rather than thermal ionization,
- (b) the transition of H to H(1/4) being the source of the 10.1 nm cutoff EUV continuum radiation observed from interstellar medium,
- (c) the hydrino continuum radiation being the source of the diffuse ubiquitous EUV and soft X-ray cosmic background, the radiation source behind the observation that diffuse Ha emission is ubiquitous throughout the Galaxy and widespread sources of flux shortward of 912 Å are required, and the source of ionization of the interstellar medium (ISM) wherein a large component of the baryonic matter of the universe is in the form of WHIM (warm-hot ionized media) in the absence of a conventional ionizing energy source,

Hydrino® power source in the Sun's corona

# Optical Power Measurement Using NIST Standards Over 10-800 nm Region: Spectral Emission in the High Energy Region Only

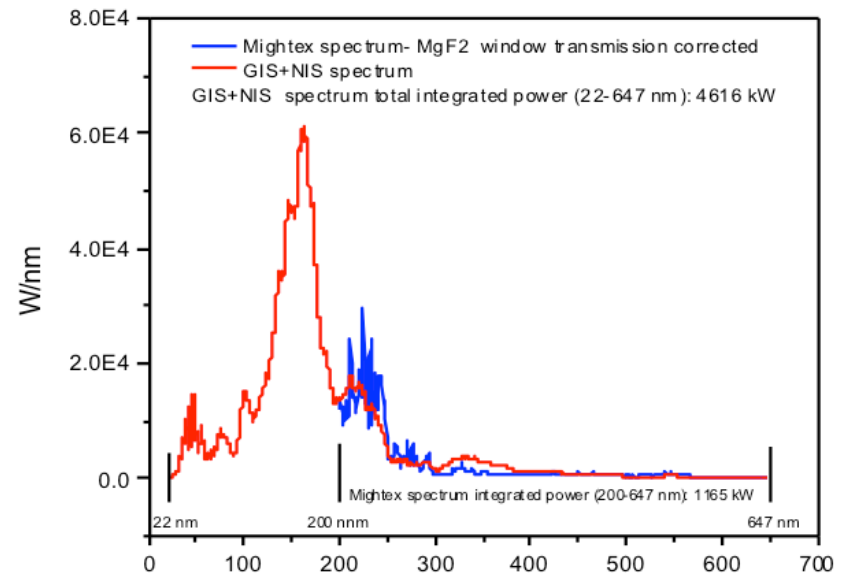

Validated Hydrino Reaction's Extraordinary High-Energy Continuum Light and Optical Power at over 1,000,000W Levels

The continuum radiation with the predicted 10.1 nm cutoff confirms the production of H(1/4).

# 4.6 MW Characteristic H to H(1/4) Transition EUV Continuum Radiation with a Predicted 10.1 nm Cutoff

- Hydrated silver shots comprising a source of H and HOH catalyst were ignited by passing a low voltage, high current through the shot to produce explosive plasma that emitted brilliant light predominantly in the short-wavelength 10 to 300 nm region.
- The peak power of 20 MW and time-average power of 4.6 MW was measured using absolute spectroscopy over the 22.8-647 nm region wherein the optical emission energy was 250 times the applied energy.
- The wavelength calibrated and absolute intensity calibrated spectrum (10-45 nm) of the emission of hydrated silver shots recorded on the GIS with a Zr filter showed the EUV continuum cutoff at *10.1 nm that matches dark matter emission*.

# Massive Ionization Determined by Stark Broadening at High Pressure

- Stark broadening of the H alpha line of 1~1.3 nm corresponds to an electron density of  $2.4\text{-}3.5 \times 10^{23}/\text{m}^3$ .
- The SunCell<sup>®</sup> gas density was calculated to be  $2.5 \times 10^{25}$  atoms/ $\text{m}^3$  based on an argon-H<sub>2</sub> pressure of 800 Torr and temperature of 3000K.
- The corresponding ionization fraction was about 10%.
- Given that argon and H<sub>2</sub> have ionization energies of about 15.5 eV and a recombination lifetime of less than 100 us at high pressure, the power density to sustain the ionization is

R. Mills, Y. Lu, R. Frazer, "Power Determination and Hydrino Product Characterization of Ultra-low Field Ignition of Hydrated Silver Shots", Chinese Journal of Physics, Vol. 56, (2018), pp. 1667-1717.

$$P = \left( \frac{3.5 \times 10^{23} \text{ electrons}}{\text{m}^3} \right) (15.5 \text{ eV}) \left( \frac{1.6 \times 10^{-19} \text{ J}}{\text{eV}} \right) \left( \frac{1}{10^{-4} \text{ s}} \right) = \frac{8.7 \times 10^9 \text{ W}}{\text{m}^3}$$

# Energetic Signatures

In addition to hydrogen line broadening, other signatures of the energetics of the hydride reaction are chemically generated or so called resonance transfer (RT) plasmas, plasma afterglow, high optical output power, and an inverted hydrogen population.

- 70 mg hydrated silver shot comprising a source of H and HOH catalyst were ignited by passing a low voltage, high current through the shot.
- 
- Extraordinary effects consisting of EUV emissions, explosively formed plasma fields, EMP effects and blast effects which cannot be explained through conventional chemistry and physics.
- 
- Based on the shockwave propagation velocity and the corresponding pressure, the high-current ignition of water in a silver matrix was measured to produce a shock wave that was equivalent to about 10 times more moles of gunpowder.

R. Mills, Y. Lu, R. Frazer, "Power Determination and Hydrino Product Characterization of Ultra-low Field Ignition of Hydrated Silver Shots", Chinese Journal of Physics, Vol. 56, (2018), pp. 1667-1717.

# Hydrino Reaction with Explosive Power

# Chemically-Generated RT Plasma

- Hydrogen Plasmas Formed with Incandescently Heating of Hydrogen Gas in the Presence of Trace Amounts of Potassium Carbonate.

H. Conrads, R. Mills, Th. Wrubel, "Emission in the Deep Vacuum Ultraviolet from a Plasma Formed by Incandescently Heating Hydrogen Gas with Trace Amounts of Potassium Carbonate," *Plasma Sources Science and Technology*, Vol. 12, (2003), pp. 389-395.

# Experimental Set-up for Chemically-Generated RT Plasma

# Inverted Hydrogen Population

The VUV spectra (900–1300 Å) of the cell emission from hydrogen microwave plasma (dotted line) and the  $\text{KNO}_3\text{--H}_2$  rt-plasma (solid line) with an inverted Lyman population.

R. L. Mills, P. Ray, "Stationary Inverted Lyman Population Formed from Incandescently Heated Hydrogen Gas with Certain Catalysts," J. Phys. D, Applied Physics, Vol. 36, (2003), pp. 1504–1509.

# Plasma Afterglow

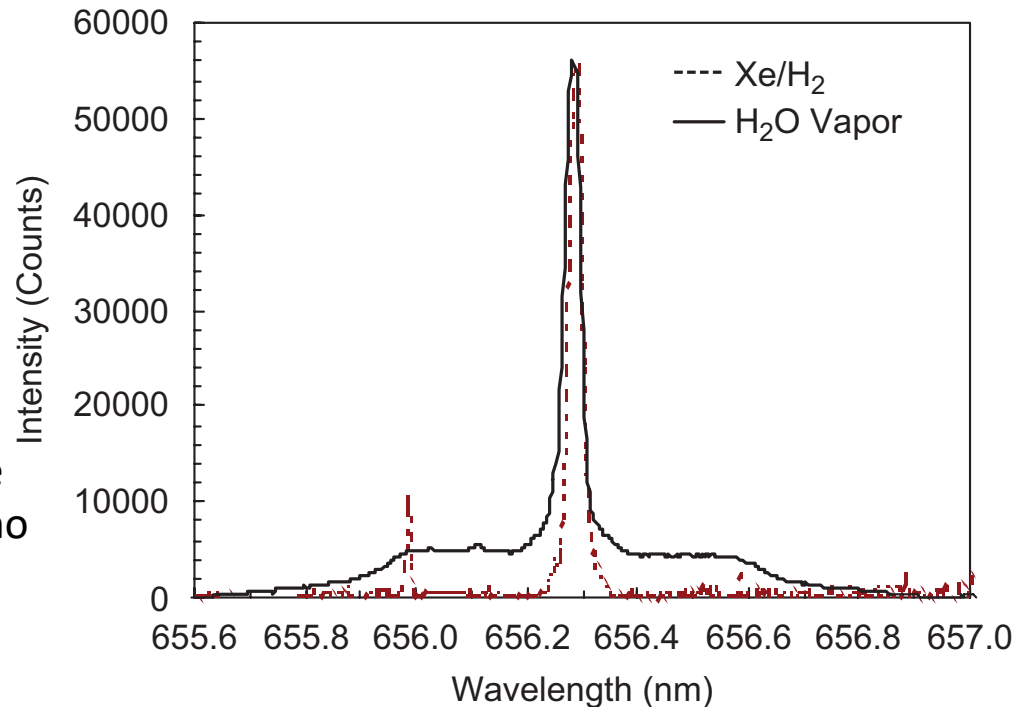

Emission of the cell as a function of time while the filament current was turned off and on. The plasma decay with no electric field present followed the decay of atomic hydrogen from the filament dissociator. Upon restoration of the filament temperature, dissociation and the plasmas resumed.

# Extraordinary Doppler Broadening of the Balmer $\alpha$ Line at Low Pressure Due to the Hydrino Reaction

- From the width of the emitted Balmer lines, it was found that low-pressure capacitively coupled radio frequency (rf) water-vapor plasmas showed the presence of both slow and fast excited hydrogen atoms.
- The typical slow component was independent of time.
- A new phenomenon, an extraordinary fast Doppler broadened component (130–150 eV) that increases to a significant portion of the Balmer emission with time, was also observed.
- These studies demonstrate excessive line broadening in the absence of an observable effect attributable to a strong electric field since the xenon–hydrogen plasma emission showed no broadening.
- To conserve energy during the resonant energy transfer of 81.6 eV ( $3 \times 27.2$  eV) from H to HOH catalyst to form  $H(1/4)$ , the resulting protons gain high kinetic energy and result in fast H emission with proton-electron recombination.

The Balmer  $\alpha$  line width profile recorded on water-vapor and Xe/H<sub>2</sub> (90/10%) rf plasmas at matched conditions of no-flow, 100 mTorr, 200 W, and 4-h plasma duration.

R. L. Mills, B. Dhandapani, K. Akhtar, "Excessive Balmer  $\alpha$  Line Broadening of Water-Vapor Capacitively-Coupled RF Discharge Plasmas," Int. J. Hydrogen Energy, Vol. 33, (2008), 802–815.

## Fast H Continued: Excessive Doppler hydrogen line broadening in low pressure H<sub>2</sub> discharge corresponding to fast H atom with energies of 100 eV wherein H atoms serve as a catalyst and a reactant to form hydrinos.

The 656.3 nm Balmer  $\alpha$  line width recorded with the Jobin Yvon Horiba 1250 M spectrometer parallel to the electric field. Even though hydrogen ions were accelerated away from the detector, a symmetrical emission profile was observed indicating that the broadening was not dependent on the electric field. The line profile recorded on a 200 mTorr H<sub>2</sub> pinch plasma showed a trimodal distribution wherein 18% and 33% of the hydrogen in the excited  $n = 3$  state was fast with an average hydrogen atom energy of 98 eV and 8.8 eV, respectively, compared to 1.3 eV for the slow population.

# Fast H Continued

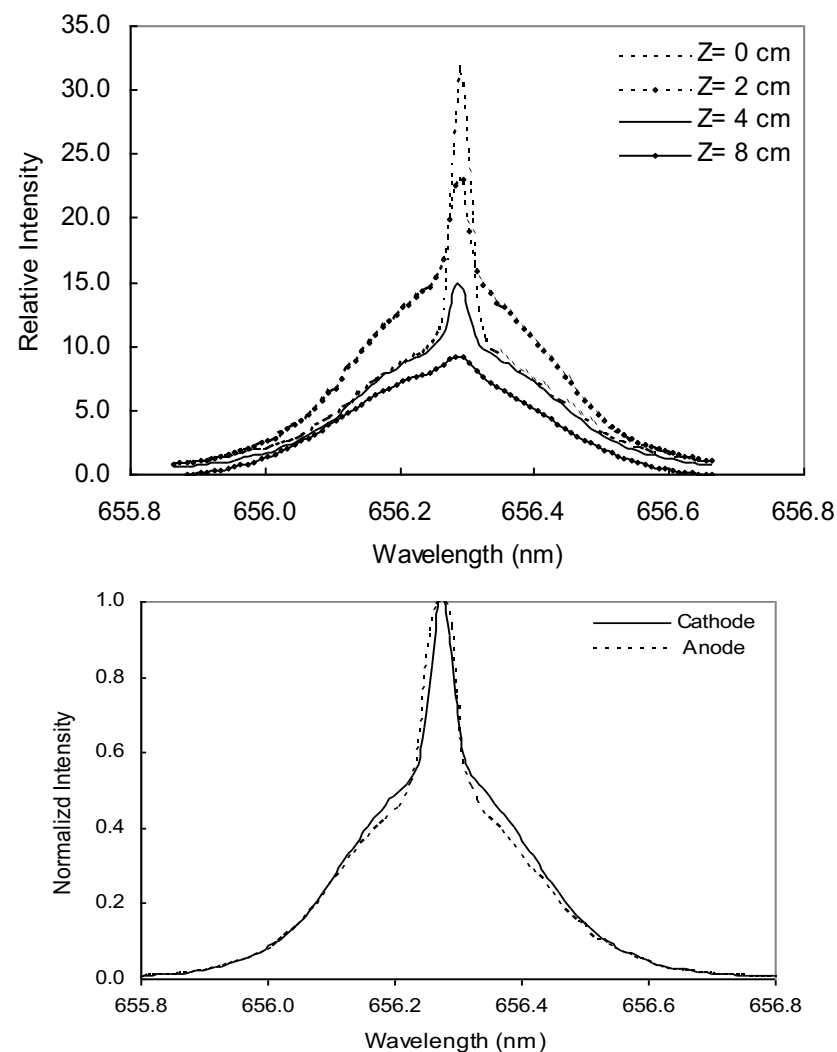

Doppler Balmer alpha line broadening is observed with hydrogen addition to argon plasma due the presence of oxygen in argon. The oxygen is present since it co-condenses with liquid argon during purification from the atmosphere. Hydrogen reacts with trace oxygen to form HOH that serves as the hydrino catalyst for atomic H of the argon-H<sub>2</sub> plasma.

Axial scan of the 656.3 nm Balmer  $\alpha$  line width recorded on a 1 Torr *Ar* /H<sub>2</sub> (95/5%) DC plasma discharge with needle-like electrodes at 400 V and 20 mA showing 80% of the hydrogen in excited n=3 state was fast with an average hydrogen atom energy of 40 eV, compared to < 0.5 eV for the slow population.

The 656.3 nm Balmer  $\alpha$  line width recorded end-on (parallel to the electric field) on a 1 Torr *Ar* /H<sub>2</sub> (95/5%) DC plasma discharge with needle-like electrodes at 400 V and 20 mA. Both views looking towards the cathode as well as the anode show a symmetrical emission profile. Fast hydrogen atoms have energies in the range of 38-40 eV.

Phys. D: Appl. Phys., Vol. 42, Issue 13 (2009), 135207 (12pp).

# Commercial Differential Scanning Calorimeter Power Measurement on Hydrino Reaction Solid Fuels

Exchange reactions of the anions between an alkali hydroxide and halide (e.g.  $\text{Cu}(\text{OH})_2 + \text{FeBr}_2$ ) as well as dehydration reactions of metal oxyhydroxides (e.g.  $\text{FeOOH}$ ) create HOH catalyst and H as transient species that react to form hydrinos.

These hydrino solid fuels release thermal energy in significant excess than possible according to enthalpy balance due to conventional known chemical reactions.

Independently validated by scientists at Perkin Elmer, Setaram, University of Illinois, Norte Dane, and Auburn University. (<https://brilliantlightpower.com/validation-reports/>)

Hydrino products are observed by multiple analytical techniques.

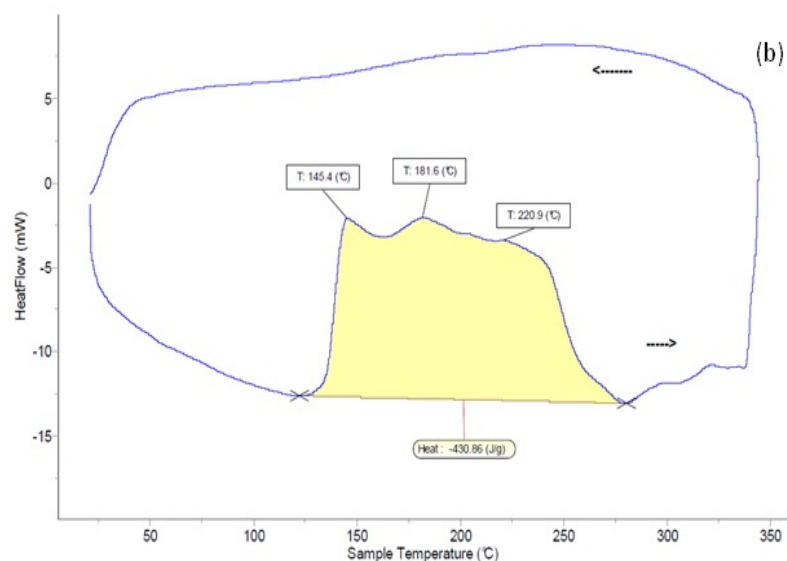

Figure – (a) DSC (Setaram DSC131) performed on  $\text{Cu}(\text{OH})_2 + \text{CuBr}_2$  by Setaram. The theoretical energy was -39.8 J/g based on the limiting reagent such that the DSC exothermic energy of -323.1 J/g corresponded to an energy gain of 8.1 times the maximum theoretical from conventional chemistry; (b) Duplicate DSC performed on  $\text{Cu}(\text{OH})_2 + \text{CuBr}_2$  by Setaram. The theoretical energy was -39.8 J/g based on the limiting reagent such that the DSC exothermic energy of -430.9 J/g corresponded to an energy gain of 10.8 times the maximum theoretical from conventional chemistry.

# Hydrino Reaction Used to Directly Produce Electrical Power in BrLP's CIHT® Electrochemical Cell

- CIHT cells, such as one comprising a MoCu hydrogen permeable membrane anode, NiO cathode, a LiOH-LiBr eutectic mixture as the electrolyte, and MgO matrix exploit hydrino formation as a half-cell reaction to serve as a new electrical energy source wherein HOH catalyst formed by an oxidation reaction of  $\text{OH}^-$  at a hydrogen anode.
- The cells were operated under intermittent  $\text{H}_2\text{O}$  electrolysis to generate H at the anode and then discharged to form hydrinos wherein  $\text{H}_2\text{O}$  vapor as well as some  $\text{O}_2$  was supplied from the atmosphere in open cells.
- Net electrical production over the electrolysis input and hydrogen supplied to the anode measured using an Arbin BT 2000 was multiples of the electrical input that in most cases exceed the input by a factor of about 2 at about  $10 \text{ mW/cm}^2$  anode area over months of continuous operation.
- The predicted molecular hydrino  $\text{H}_2(1/4)$  was spectroscopically identified as a product of CIHT cells.

# E-beam Emission Hydrino $H_2(1/4)$ Gas Rotational P Branch

Of the noble gases, argon uniquely contains trace hydrino gas due to contamination during purification. Argon and oxygen co-condense during cryo-distillation of air and the oxygen is removed by reaction with hydrogen on a recombination catalyst such as platinum whereby hydrino is formed during the recombination reaction due to the subsequent reaction of HOH catalyst with H. The known peaks are H I, O I, O<sub>2</sub> bands. The unknown peaks match molecule hydrino ( $H_2(1/4)$  P branch) with no other unassigned peaks present in the spectrum.

The small satellite lines match the rotational spin-orbital splitting energies that were also observed by Raman spectroscopy. The spin-orbital splitting energies due to rotation of  $m528\text{ cm}^{-1}$ ,  $m = 1, 1.5$  wherein 1.5 involves the  $m = 0.5$  and  $m = 1$  splittings. It is extraordinary that the EPR, Raman, and electron-beam excitation spectra give the same information about the structure of molecular hydrino in energy ranges that differ by reciprocal of the  $H_2(1/4)$  diamagnetic susceptibility coefficient:  $1/7 \times 10^{-7} = 1.4 \times 10^6$  wherein the induced diamagnetic orbital magnetic moment active during EPR was replaced by the orbital molecular rotational magnetic moment active during Raman and electron-beam excitation of rotational transitions.

N101403/2004

# E-beam Emission Hydrino $H_2(1/4)$ Gas Ro-vibrational P Branch

The ro-vibrational spectrum of  $H_2(1/4)$  was observed by 6 keV electron beam excitation of argon gas at atmospheric pressure wherein the electron beam passed through a silicon nitride window of the plasma cell. The cutoff of 8.2 eV and the line spacing of 0.25 eV matched the  $v = 1$  to  $v = 0$  vibrational transition with the P-branch rotational spectrum of  $H_2(1/4)$ .

## HOH-Argon E-beam Emission Linear Regression

# E-beam Emission Hydrino $H_2(1/4)$ Gas Ro-vibrational P Branch

$H_2(1/4)$  gas of an argon/ $H_2(1/4)$  mixture formed by recombination of hydrogen and oxygen on a supported noble metal catalyst in an argon atmosphere was enriched on a HayeSep<sup>®</sup> D chromatographic column cooled to a cryogenic temperature in a liquid argon. The  $H_2(1/4)$  enrichment caused a dramatic increase in the ro-vibrational P branch of  $H_2(1/4)$  observed by e-beam excitation emission spectroscopy. The spectrum was obtained at room temperature.

# E-beam Emission Hydrino $H_2(1/4)$ Gas Ro-vibrational P Branch

Ultraviolet emission spectrum from electron beam excitation of  $H_2(1/4)$  gas released from heating FeOOH: $H_2(1/4)$ . The cutoff of 8.2 eV and the line spacing of 0.25 eV matched the  $\nu = 1$  to  $\nu = 0$  vibrational transition with the P-branch rotational spectrum of  $H_2(1/4)$ .

# E-beam Emission Hydrino $H_2(1/4)$ Gas Ro-vibrational P Branch

The ro-vibrational spectrum of  $H_2(1/4)$  that was observed as ultraviolet emission lines by 12 keV electron beam excitation of thermally released GaOOH: $H_2(1/4)$  gas flowed at atmospheric pressure from a cryogenic chromatography wherein the electron beam passed through a silicon nitride window of the plasma cell. The cutoff of 8.2 eV and the line spacing of 0.25 eV matched the  $\nu = 1$  to  $\nu = 0$  vibrational transition with the P-branch rotational spectrum of  $H_2(1/4)$ .

# Matrix-Shifted E-beam Emission

## Hydrino $H_2(1/4)$ Ro-vibrational P Branch ( $H_2(1/4)$ in KCl matrix)

Ultraviolet emission spectrum from electron beam excitation of KCl that was impregnated with hydrino reaction product gas showing the  $H_2(1/4)$  ro-vibrational P branch in the crystalline lattice.

## E-beam Emission Linear Regression

R. L. Mills, J. He, Z. Chang, W. Good, Y. Lu, B. Dhandapani, "Catalysis of Atomic Hydrogen to Novel Hydrogen Species  $H(1/4)$  and  $H_2(1/4)$  as a New Power Source," Int. J. Hydrogen Energy, Vol. 32(13), (2007), pp. 2573–2584.

# Vibrational and Rotational Predicted Energies

- Hydrogen molecular vibrational energy,  $E_{vib}$ , for the  $v = 0$  to  $v = 1$  transition of hydrogen type molecules  $H_2(1/p)$  is

$$E_{vib} = p^2 \times 0.515912 \text{ eV}$$

- The rotational energies,  $E_{rot}$ , for the  $J$  to  $J+1$  transition of hydrogen molecules  $H_2(1/p)$  is

$$E_{rot} = p^2 \times (J+1) \times 0.01509 \text{ eV}$$

- The emitters in both HOH-Ar and a solid impregnated with hydrino gas match emission spacing's and match the rotationally predicted energies for  $H_2(1/4)$ . The emitter in HOH-Ar matches the vibrationally predicted energy for  $H_2(1/4)$ .

H2(1/4) in Ar	Experimental Value (eV)	Theoretical Value (eV)
Vibrational Energy ( $v = 0$ to $1$ )	8.2675	8.2544
Rotational Energy ( $J = 0$ to $1$ )	0.2596	0.2414

H2(1/4) in KCl	Experimental Value (eV)	Theoretical Value (eV)
Vibrational Energy ( $v = 0$ to $1$ )	5.7998	*
Rotational Energy ( $J = 0$ to $1$ )	0.2491	0.2414

- \*The vibrational energy for  $H_2(1/4)$  in a solid matrix is shifted due to the increased effective mass from the solid matrix interaction analogous to the cases of  $H_2$  in solid matrices such as Si and Ge as discussed in primary literature.

# Ro-vibrational P Branch from E-beam Emission of Hydrino $H_2(1/4)$ in KCl Matrix is Dependent on Temperature that Confirms Ro-Vibrational Assignment

Emission spectra were recorded using a McPherson grazing incidence EUV spectrometer and a CCD detector during electron-beam excitation of KCl getter exposed to thermal decomposition gas from  $Ga_2O_3:H_2(1/4)$  from the SunCell® at 3 keV and 30  $\mu A$ . The series of peaks matches the  $H_2(1/4)$  theoretical ro-vibrational peaks to within an error of less than 1%. The elimination of the emission while cryocooling and its return at lower intensity at room temperature confirmed that the source of the emission was  $H_2(1/4)$  ro-vibration with some  $H_2(1/4)$  diffusion loss by thermally cycling.

# Raman Confirmation of Molecular Hydrino of $H_2(1/4)$ in KCl Matrix Ro-Vibrational Band

- The spin of the molecular hydrino molecular orbital (MO) is  $\frac{1}{2}(\uparrow\uparrow+\downarrow\downarrow)$  where each arrow designates the spin vector of one electron.
- Due to the unique electronic structure of  $H_2(1/4)$  comprising a paired and an unpaired electron in the  $H_2(1/4)$  MO requiring spin  $\frac{1}{2}$  conservation during transitions, the excitation and decay of ro-vibration states of molecular hydrino involve two-photons, each of  $\frac{1}{2}$  the energy of the ro-vibrational state.
- The Raman spectrum of KCl getter exposed to gas from the thermal decomposition of  $Ga_2O_3:H_2(1/4)$  collected from the SunCell® wherein the spectrum was recorded with a Horiba Jobin Yvon LabRam ARAMIS spectrometer with a 325nm laser and a 1200 grating over a range of 8000-19,000  $cm^{-1}$  Raman shift.
- The corresponding emission spectrum matched the  $\frac{1}{2}$  - energy emission spectrum of the 260nm e-beam band comprising rotational transitions of the matrix-shifted  $v=1$  to  $v=0$  vibrational transition.
- A long-pass edge filter confirmed the assignments wherein the series of peaks match the theoretical energies to within an error of less than 1%.

# Comparison of Spectra of Alkali Hydroxide and Halide Mixture with Spectra of 780 nm Laser Raman Active and Inactive Powders Validated at ThermoFisher

The spectra of the Alkali Hydroxide and Halide Mixture samples shown in a common scale along with reference spectra of KBr (Raman inactive, transparent) and “Splenda” (Raman active, white) powders measured at exactly the same measurement conditions, i.e. the same vial and the measurement parameters. Note: No negative peak at 2305  $\text{cm}^{-1}$  is observed in the reference spectra.

# Alkali Hydroxide and Halide Mixture Spectra of 780 nm Laser Raman Active Powders replicated at University of Texas El Paso

The Raman forbidden  $\text{H}_2(1/4) J = 0$  to  $J = 1$  rotational transition was observed at  $2300 \text{ cm}^{-1}$  due to a surface enhanced inverse Raman effect (SEIRE). The free rotor energy of  $0.2414 \text{ eV}$  ( $1940 \text{ cm}^{-1}$ ) has a barrier of about  $360 \text{ cm}^{-1}$  due to interactions with the solid matrix.

# Raman Confirmation of Molecular Hydrino of $H_2(1/4)$ Rotational Energy Allowed by the Surface Enhanced Inverse Raman Effect (SEIRE)

The Raman spectrum obtained on a In metal foil exposed to the product gas from a series of solid fuel ignitions under argon, each comprising 100 mg of Cu mixed with 30 mg of deionized water. Using the Thermo Scientific DXR SmartRaman spectrometer and the 780 nm laser, the spectrum showed an inverse Raman effect peak at  $1982\text{ cm}^{-1}$  that matches the free rotor energy of  $H_2(1/4)$  (0.2414 eV).

R. Mills J. Lotoski, "H<sub>2</sub>O-based solid fuel power source based on the catalysis of H by HOH catalyst", Int'l J. Hydrogen Energy, Vol. 40, (2015), 25-37.

# SEIRE Raman Confirmation of Molecular Hydrino of $H_2(1/4)$ Rotational Energy

Raman spectra obtained using the Thermo Scientific DXR SmartRaman spectrometer and the 780 nm laser on copper electrodes pre and post ignition of a 80 mg silver shot comprising 1 mole%  $H_2O$ , wherein the detonation was achieved by applying a 12 V 35,000 A current with a spot welder. The spectra showed an inverse Raman effect peak at about 1940  $cm^{-1}$  that matches the free rotor energy of  $H_2(1/4)$  (0.2414 eV).

# XPS Total Binding Energy of H<sub>2</sub>(1/4)

The XPS spectra of the hydrino Mo web compound having a peak at 496 eV assigned to H<sub>2</sub>(1/4) wherein other possibilities such Na, Sn, and Zn were eliminated since only Mo, O, and C peaks are present and other peaks of the candidates are absent. Mo 3s which is less intense than Mo3p was at 506 eV with additional samples that also showed the H<sub>2</sub>(1/4) 496 eV peak. A. Survey scan. B. High resolution scan in the region of the 496 eV peak of H<sub>2</sub>(1/4).

# XPS Confirmation of Molecular Hydrino of H<sub>2</sub>(1/4) Binding Energy

The XPS spectra on copper electrodes post ignition of a 80 mg silver shot comprising 1 mole% H<sub>2</sub>O, wherein the detonation was achieved by applying a 12 V 35,000 A current with a spot welder. The peak at 496 eV was assigned to H<sub>2</sub>(1/4) wherein other possibilities such Na, Sn, and Zn were eliminated since the corresponding peaks of these candidates are absent. Raman post detonation spectra showed an inverse Raman effect peak at about 1940 cm<sup>-1</sup> that matches the free rotor energy of H<sub>2</sub>(1/4) (0.2414 eV).

Solid Fuel Reaction Product KOH + KCl heated at 80 °C was EPR Active Indicative of the Presence of  $\text{H}_2(1/4)$  Having an Unpaired Electron

SEM and Energy Dispersive X-ray Spectroscopy (EDS) of white polymeric compound  $\text{GaOOH}:\text{H}_2(1/4)$  comprising  $\text{H}_2(1/4)$  formed by dissolving  $\text{Ga}_2\text{O}_3$  collected from a hydrido reaction run in the SunCell® in 4M aqueous KOH, allowing fibers to grow, and float to the surface where they were collected by filtration. Particle size: KOH 100 nm; NaOH 40 nm. The hydrido compound is not soluble in concentrated acid (pH ~0) or concentrated base (pH ~14).

**X-ray Diffraction** of  $\text{GaOOH}:\text{H}_2(1/4)$  formed by dissolving  $\text{Ga}_2\text{O}_3$  collected from a hydrino reaction run in the SunCell® in 4M aqueous KOH or 4M NaOH, allowing fibers to grow, and float to the surface where they were collected by filtration. The KOH pattern is shifted to lower  $2\theta$  relative to that of NaOH and both patterns are shifted relative to the standard pattern of GaOOH. The particle size of the compound prepared in KOH is 19.4 nm and the particle size of the compound prepared in NaOH is 24.4 nm.

# Transmission Electron Microscopy (TEM) Analysis for GaOOH:H<sub>2</sub>(1/4) and GaOOH Control

- Talos F200X Scanning/Transmission Electron Microscope used for imaging and selected area electron diffraction (SAED).
- The GaOOH:H<sub>2</sub>(1/4) sample was observed by TEM to comprise two different morphological and crystalline forms of GaOOH.
- Observed morphologically polymeric crystals comprising hexagonal crystalline structure were very sensitive to the TEM electron beam; whereas rods having orthorhombic crystalline structure were not electron beam sensitive.
- The rod crystals' morphology and crystalline structure matches those of the literature for control GaOOH that lacks molecular hydrino inclusion.
- XRD crystal system for Tsumgallite (GaOOH) is Orthorhombic.

Polymeric GaOOH:H<sub>2</sub>(1/4) TEM Imaging

GaOOH:H<sub>2</sub>(1/4) SAED Hexagonal Pattern

Rod-shaped GaOOH:H<sub>2</sub>(1/4) TEM Imaging

GaOOH:H<sub>2</sub>(1/4) SAED Orthorhombic Pattern

# Ga Ion ToF-SIMS

Negative Spectrum showing hydride ion as a dominant ion fragment due to the stability of hydride ion. The TOF-SIMS confirms the H content supporting the molecular hydride component. The composition by energy dispersive X-ray spectroscopy (EDS) and Rutherford backscattering spectrometry (RBS) was  $\text{GaO}_{2.1}$  and  $\text{GaO}_{1.68}\text{H}_{1.32}$ , respectively. No hydrocarbons (HC) above adventitious HC were present that could give rise to an EPR spectrum.

## Negative Spectrum

Mass range (0-100 amu)

# Ga Ion ToF-SIMS

Positive spectrum recorded on the GaOOH:H<sub>2</sub>(1/4). Only potassium and gallium were observed in the positive spectrum. No transition metals were present that could give rise to an EPR spectrum.

## Positive Spectrum

Mass range (0-100 amu)

Rutherford Backscattering Spectrometry (RBS) was performed on the  $\text{GaOOH}:\text{H}_2(1/4)$ . The RBS result identified the composition as  $\text{GaO}_{1.68}\text{H}_{1.32}$  corresponding to an excess H content, some of which is hydrino hydrogen based on the results of other analytical tests.

	"RBS" Thickness [Å]	Atomic Concentrations [at%]			Assumed Density [at/cc]
		Ga	O	H	
BULK	-	25	42	33	8.56E22

# XPS Total Binding Energy of H<sub>2</sub>(1/4)

GaOOH:H<sub>2</sub>(1/4) was formed by dissolving Ga<sub>2</sub>O<sub>3</sub> collected from a hydrido reaction run in the SunCell® in 4M aqueous KOH, allowing fibers to grow, and float to the surface where they were collected by filtration.

The XPS spectrum of GaOOH:H<sub>2</sub>(1/4) recorded using a nonmonochromatic Mg K $\alpha$  (1254 eV) excitation source with the XPS spectra recorded using a SPECS GmbH system with a PHOIBOS 150 hemispherical energy analyzer. The H<sub>2</sub>(1/4) total energy peak was observed at 496 eV wherein other possibilities such as Sn, W, and Ir were eliminated since the corresponding peaks of these candidates were absent. These alternative elements were also eliminated by ToF-SIMS, EDS, and XRD. Cu is from the TEM grid used to mount the fibers.

# Solution Room Temperature Evaporation Rate Measurement of GaOOH:H<sub>2</sub>(1/4) Added to H<sub>2</sub>O Versus Controls Shows a Higher Evaporation Rate

## Quantized Magnetic Flux Linkage in Units of $h/2e$ Observed by Visible Emission Spectroscopy of $H^-(1/2)$ , Electron Paramagnetic Resonance Spectroscopy of $H_2(1/4)$ , and Raman Spectroscopy of $H_2(1/4)$ .

- The hydrino hydride ion comprising a paired and unpaired electron in a common atomic orbital demonstrated the phenomena of flux linkage in quantized units of  $h/2e$ .
- The pattern of integer-spaced peaks of the EPR spectrum of  $H_2(1/4)$  is very similar to the periodic pattern observed in the high-resolution visible spectrum of the hydrino hydride ion.
- Moreover, the same phenomena were observed when the rotational energy levels of  $H_2(1/4)$  were excited by laser irradiation during Raman spectroscopy.
- It is extraordinary that the EPR and Raman spectra give the same information about the structure of molecular hydrino in energy ranges that differed by reciprocal of the  $H_2(1/4)$  diamagnetic susceptibility coefficient:  $1/7 \times 10^{-7} = 1.4 \times 10^6$ , wherein the induced diamagnetic orbital magnetic moment active during EPR was replaced by the orbital molecular rotational magnetic moment active during Raman.

# Mechanism of Quantized Magnetic Flux Linkage in Units of $h/2e$ Observed by Electron Paramagnetic Resonance Spectroscopy of $H_2(1/4)$

- $H_2(1/4)$  comprises an unpaired electron which enables the electronic structure of this unique hydrogen molecular state to be determined by electron paramagnetic resonance (EPR) spectroscopy.
- Specially, the  $H_2(1/4)$  EPR spectrum comprises a principal peak with a g-factor of 2.0046386 that is split into a series of pairs of peaks with members separated by spin-orbital coupling energies that are a function of the corresponding electron spin-orbital coupling quantum numbers.
- The unpaired electron magnetic moment induces a diamagnetic moment in the paired electron of the  $H_2(1/4)$  molecular orbital based on the diamagnetic susceptibility of  $H_2(1/4)$ .
- The corresponding magnetic moments of the intrinsic paired-unpaired current interactions and those due to relative rotational motion about the internuclear axis give rise to the spin-orbital coupling energies.
- The EPR spectral results confirmed the spin-orbital coupling between the spin magnetic moment of the unpaired electron and an orbital diamagnetic moment induced in the paired electron by the unpaired electron that shifted the flip energy of the spin magnetic moment.
- Each spin-orbital splitting peak was further sub-split into a series of equally spaced peaks that matched integer fluxon energies that are a function of the electron fluxon quantum number corresponding to the number of angular momentum components involved in the transition.
- The evenly spaced series of sub-splitting peaks was assigned to flux linkage in units of the magnetic flux quantum  $h/2e$  during the coupling between the paired and unpaired magnetic moments while a spin flip transition occurred.
- Additionally, the spin-orbital splitting increased with spin-orbital coupling quantum number on the downfield side of the series of pairs of peaks due to magnetic energies that increased with accumulated magnetic flux linkage by the molecular orbital.

# Mechanism of Quantized Magnetic Flux Linkage in Units of $h/2e$ Observed by Raman Spectroscopy of $H_2(1/4)$

- The Raman transition rotation of  $H_2(1/4)$  is about a semiminor axis perpendicular to the internuclear axis.
- The intrinsic electron spin angular momentum aligns either parallel or perpendicular to the corresponding molecular rotational angular momentum along the molecular rotational axis, and a concerted rotation of the spin current occurs during the molecular rotational transition.
- The interaction of the corresponding magnetic moments of the intrinsic spin and the molecular rotation give rise to the spin-orbital coupling energies that are a function of the spin-orbital quantum number.
- The Raman spectral results confirmed the spin-orbital coupling between the spin magnetic moment of the unpaired electron and the orbital magnetic moment due to molecular rotation.
- The energies of the rotational transitions were shifted by these spin-orbital coupling energies as a function of the corresponding electron spin-orbital coupling quantum numbers.
- Molecular rotational peaks shifted by spin-orbital energies are further shifted by integer fluxon linkage energies with each energy corresponding to its electron fluxon quantum number dependent on the number of angular momentum components involved in the rotational transition.
- The observed sub-splitting or shifting of Raman spectral peaks was assigned to flux linkage in units of the magnetic flux quantum  $h/2e$  during the spin-orbital coupling between spin and molecular rotational magnetic moments while the rotational transition occurred.
- Additionally, the fluxon sub-splitting increased with the integer number of fluxons linked on the downfield side of a series of sub-split peaks due to magnetic energies that increased with accumulated magnetic flux linkage by the molecular orbital.

# Hydrino Hydride Ion $H^-(1/2)$ Characteristic Signature

Wavelength-calibrated spectrum (3900-4090 Å) of a hydrino-reaction-plasma formed by heating  $KNO_3$  and dissociating  $H_2$  using a tungsten filament overlaid with a hydrogen microwave plasma. The emission due to  $H^-(1/2)$  formation in the bound-free region is not a continuum as in the case of ordinary hydride ion.  $H^-(1/2)$  comprises an unpaired electron such that upon the binding of a free electron by  $H(1/2)$  to form  $H^-(1/2)$ , flux is linked by  $H(1/2)$  in integer units of the magnetic flux quantum  $h/2e$ . Consequently, the bound-free spectrum comprises a series of hyperfine lines corresponding to quantized energy levels given by the sum of the fluxon energy, the spin-spin energy, and the binding energy.

R. L. Mills, J. He, Y. Lu, M. Nansteel, Z. Chang, B. Dhandapani, "Comprehensive Identification and Potential Applications of New States of Hydrogen," Int. J. Hydrogen Energy, Vol. 32(14), (2007), 2988–3009.

# High Resolution Electron Paramagnetic Resonance (EPR) Spectrum of a Molecular Hydrino (Data courtesy of prof dr Wilfred R Hagen TU Delft)

The 9.73855 GHz EPR spectrum (3445 G to 3495 G region) of a hydrino reaction product  $\text{GaOOH}:\text{H}_2(1/4)$ . This reaction product was formed by dissolving  $\text{Ga}_2\text{O}_3$  collected from a hydrino reaction run in the SunCell® in aqueous KOH, and allowing polymeric fibers to grow, and float to the surface where they were collected by filtration.

The spectrum demonstrates splitting into two main peaks at 3467.9 G and 3470.9 G corresponding to a 4.1 G separation, wherein the two main peaks comprised sub-splitting into a series of evenly separated peaks of 0.31 G separation.

Theory Chapter 16: <https://brilliantlightpower.com/GUT/GUT-CP-2020-Ed-Volume2-Web.pdf>

Wilfred R. Hagen, Randell L. Mills, "Electron Paramagnetic Resonance Proof for the Existence of Molecular Hydrino", Vol. 47, No. 56, (2022), pp. 23751-23761; <https://www.sciencedirect.com/science/article/pii/S0360319922022406>.

# High Resolution Electron Paramagnetic Resonance (EPR) Spectrum of a Molecular Hydrino

(Data courtesy of prof dr Wilfred R Hagen TU Delft)

The sub-splitting into the series of evenly spaced peaks of 0.31 G separation is apparent in the high-resolution 9.7385 GHz EPR spectrum in the region of 3464.5 G to 3468.5 G acquired at modulation amplitude of 0.025 G with averaging of 1000, 20 s scans (top) and in the corresponding filtered spectrum (bottom).

The spectra match theory identically wherein the two main peaks arise from spin-orbital coupling between the spin magnetic moment of the unpaired electron and an orbital diamagnetic moment induced in the paired electron by the flip of the spin magnetic moment.

By a common mechanism as the hydrino hydride ion, the evenly spaced series of sub-splitting peaks is due to flux linkage during the coupling between the paired and unpaired magnetic moments in units of the magnetic flux quantum  $h/2e$  while a spin flip transition occurs. The splitting energies are too low to match any prior known assignment.

The EPR spectrum of  $\text{GaOOH}:\text{H}_2(1/4)$  was replicated by Bruker using two instruments.

3503 G - 3508 G region.

# Deuterium Substitution Confirmed the Purely Electronic Spin-Orbital and Fluxon Splitting Assignments of the EPR Spectrum

- The EPR spectrum of the deuterated analog showed a singlet with no fine structure; thus, eliminating any possible nuclear splitting assignment.
- GaOOH:H<sub>2</sub>(1/4) comprised a hexagonal phase having a complex EPR spectrum of lines assigned to spin-orbital and fluxon splitting. It also comprised an orthorhombic phase having a singlet EPR spectrum.
- The g factor and profile of GaOOH:HD(1/4) matched that of the singlet of GaOOH:H<sub>2</sub>(1/4) wherein the singlet in both cases was due to the orthorhombic phase. The XRD of the deuterated analog matched that of the hydrogen analog, both comprising gallium oxyhydroxide. TEM confirmed that the deuterated analog comprised 100% orthorhombic phase. The phase preference of the deuterated analog may be due to a different hydrino concentration and kinetic isotope effect which could have also reduced the concentration.

EPR spectrum of GaOOH:HD(1/4)  
(3464.65 G - 3564.65 G) region.

SunCell® hydrino power generator comprising a single electromagnetic pump injector and electrode in an injector reservoir electrode, a vertically aligned counter electrode, and a glow discharge cell connected to a top flange to form HOH catalyst and atomic H.

# Confirmation of Molecular Hydrino $H_2(1/4)$ by Raman Spectroscopy

- Raman spectra obtained using a Horiba Jobin Yvon LabRam ARAMIS spectrometer with a 785 nm laser on a Ni foil prepared by immersion in the molten gallium of a SunCell that maintained a hydrino plasma reaction for 10 minutes. A. 2500  $cm^{-1}$  to 11,000  $cm^{-1}$  region. B. 8500  $cm^{-1}$  to 11,000  $cm^{-1}$  region.
- All of the novel high-energy emission lines matched the double transition for final rotational quantum numbers  $J'_p = 3$  and  $J'_c = 0,1,2$ .
- Corresponding spin-orbital coupling and fluxon coupling were also observed.
- The novel lines were eliminated by a Semrock long-pass edge filter (BLP01-785R-25) having an edge wavelength of 805 nm and  $T_{avg} > 93\%$  812.1 – 1200 nm placed between the sample and the detector confirming the assignment to high energy emission rather than low energy Raman transitions

(A)

(B)

# Control Sample for Confirmation of Molecular Hydrino $H_2(1/4)$ by Raman Spectroscopy

Raman spectra obtained using a Horiba Jobin Yvon LabRam ARAMIS spectrometer with a 785 nm laser on a  $Ni_3Ga$  alloy sample prepared by immersion of the Ni foil in the molten gallium of a SunCell that maintained a hydrino plasma reaction for 10 minutes. No lines were observed which confirmed that the novel lines observed in the Ni foil are real and not an artifact.

# Confirmation of Molecular Hydrino $H_2(1/4)$ by Raman Spectroscopy

Raman spectra ( $2200\text{ cm}^{-1}$  to  $11,000\text{ cm}^{-1}$ ) obtained using a Horiba Jobin Yvon LabRam ARAMIS spectrometer with a 785 nm laser on  $GaOOH:H_2(1/4)$  showing  $H_2(1/4)$  rotational transitions with spin-orbital coupling and fluxon linkage shifts.

# Confirmation of Molecular Hydrino $H_2(1/4)$ by Raman Spectroscopy

Raman spectra ( $2200\text{ cm}^{-1}$  to  $11,000\text{ cm}^{-1}$ ) obtained using a Horiba Jobin Yvon LabRam ARAMIS spectrometer with a 785 nm laser on a silver shot electrode post detonation showing  $H_2(1/4)$  rotational transitions with spin-orbital coupling and fluxon linkage shifts.

# Confirmation of Molecular Hydrino HD(1/4) by Raman Spectroscopy

Raman spectra obtained using a Horiba Jobin Yvon LabRam ARAMIS spectrometer with a 785 nm laser on GaOOH:HD(1/4). A. 2500  $\text{cm}^{-1}$  to 11,000  $\text{cm}^{-1}$  region. B. 8000  $\text{cm}^{-1}$  to 11,000  $\text{cm}^{-1}$  region. All of the novel high-energy emission lines matched the double transition for final rotational quantum numbers  $J'_p = 2(3)$  and  $J'_c = 1(0,1,2)$ . Corresponding spin-orbital coupling and fluxon coupling were also observed. The rotational peaks shifted as predicted for the change in reduced mass of HD(1/4) compared to that of  $\text{H}_2(1/4)$ .

# Confirmation of Molecular Hydroino HD(1/4) by Raman Spectroscopy

## Cont'd

# FTIR spectrum recorded on KI:H<sub>2</sub>(1/4)

- The ability of interactions with a crystalline site to permit H<sub>2</sub>(1/4) to be FTIR active due to an induced dipole was tested by embedding H<sub>2</sub>(1/4) in a KI lattice.
- The high resolution (0.5 cm<sup>-1</sup>) FTIR spectrum (490–4000 cm<sup>-1</sup>) of KI:H<sub>2</sub>(1/4) showing unique sharp peaks assigned to H<sub>2</sub>(1/4).
- A major sharp peak was observed by FTIR on KI:H<sub>2</sub>(1/4) at 1943 cm<sup>-1</sup> that matched near identically the J = 0 to J' = 1 rotational transition of H<sub>2</sub>(1/4).
- Other sharp peaks in the FTIR spectrum matched this rotational transition with spin-orbital and fluxon linkage splitting.

# The effect of the application of a magnetic field on the FTIR spectrum (200 $\text{cm}^{-1}$ to 8000 $\text{cm}^{-1}$ ) recorded on $\text{GaOOH}:\text{H}_2(1/4)$ .

- Infrared transitions of  $\text{H}_2(1/4)$  are forbidden because of its symmetry that lacks an electric dipole moment. However,  $\text{H}_2(1/4)$  has an unpaired electron resulting in the observation of rotational infrared excitation by coupling to the magnetic dipole of  $\text{H}_2(1/4)$ , enhanced by an external applied magnetic field as well as through spin-orbital coupling.
- The application of a magnetic field gave rise to a significantly increased FTIR peak at 4164  $\text{cm}^{-1}$ , too high an energy to be a known peak considering that  $\text{H}_2$  was eliminated as possibility. The peak is an exact match to the concerted rotational transition  $J=0$  to  $J'=1$  with spin-orbital coupling.
- In addition, a substantial increased intensity of a sharp peak at 1801  $\text{cm}^{-1}$  was observed. This peak was not observed in the FTIR of control  $\text{GaOOH}$ . The peak matched the lowest energy concerted rotational transition with spin orbital and fluxon linkage coupling.

## The effect of the application of a magnetic field on the FTIR spectrum recorded on GaOOH:H<sub>2</sub>(1/4) Cont'd.

FTIR spectra (4000-8500 cm<sup>-1</sup>) recorded on GaOOH:H<sub>2</sub>(1/4) showed addition peaks having the very high energies of 4899 cm<sup>-1</sup>, 5318 cm<sup>-1</sup>, and 6690 cm<sup>-1</sup> matching H<sub>2</sub>(1/4) rotational and spin-orbital transitions wherein the intensity was increased due to the applied magnetic field, Control GaOOH showed no features.

# Confirmation of Molecular Hydrino $\text{H}_2(1/4)$ by Its Raman Allowed $J = 0$ to $J = 2$ Rotational Transition

The Raman allowed  $\text{H}_2(1/4)$   $J = 0$  to  $J' = 2$  rotational transition with spin orbital coupling was observed on  $\text{Fe}_2\text{O}_3:\text{H}_2(1/4)$  the product of  $\text{FeOOH}$  solid fuel hydrino reaction product using a Horiba Jobin Yvon LabRam ARAMIS with a 785 nm laser. The peak at  $1062\text{ cm}^{-1}$  is due to silicate of the Raman slide and the other lines are multi-order 785 nm laser lines. Due to the extraordinary high energy, the peak assigned to  $\text{H}_2(1/4)$  rotation cannot be assigned to any prior known compound. (R. Mills, J. Lotoski, W. Good, J. He, "Solid Fuels that Form HOH Catalyst," Int'l J. Hydrogen Energy, Vol. 39 (2014), pp. 11930–11944 DOI: 10.1016/j.ijhydene.2014.05.170.0

The Raman spectrum ( $3500\text{ cm}^{-1}$  to  $8000\text{ cm}^{-1}$ ) obtained using a Horiba Jobin Yvon LabRam ARAMIS spectrometer with a  $785\text{ nm}$  laser on solid  $\text{FeOOH}$  powder prepared by ball milling for 10 hours showing the series of peaks assigned to the second and third order emission of fluxon linkages during the  $\text{H}_2(1/4)$  double rotational and spin-orbital transition for final rotational, spin-orbital, and fluxon quantum numbers  $J'_p=3$  and  $J'_c=2$ ,  $m=-1.5$ , and  $m_{\Phi_{3/2}}=2$ , respectively.

The Raman spectrum (3420  $\text{cm}^{-1}$  to 4850  $\text{cm}^{-1}$ ) obtained using a Horiba Jobin Yvon LabRam ARAMIS spectrometer with a 785 nm laser on solid web-like fibers (Fe web) prepared by wire detonation of an ultrahigh purity Fe wire in air maintained with 20 Torr of water vapor showing a periodic series of peaks assigned to the second order emission of fluxon linkages during the  $\text{H}_2(1/4)$  double rotational and spin-orbital transition for final rotational, spin-orbital, and fluxon quantum numbers  $J'_p=3$  and  $J'_c=2$ ,  $m=-1.5$ , and  $m_{\Phi_{3/2}}=2$ , respectively.

The Raman spectrum (6000  $\text{cm}^{-1}$  to 7600  $\text{cm}^{-1}$ ) obtained on solid  $\text{FeOOH:H}_2(1/4)$  showing the details of the series assigned to the third order emission of fluxon linkages during the  $\text{H}_2(1/4)$  double rotational and spin-orbital transition for final rotational, spin-orbital, and fluxon quantum numbers  $J'_p=3$  and  $J'_c=2$ ,  $m=-1.5$ , and  $m_{\Phi_{3/2}}=2$ , respectively.

Raman anti-Stokes ( $-50\text{ cm}^{-1}$  to  $-8000\text{ cm}^{-1}$ ) of the ball milled FeOOH sample recorded with 25% and 50% 300 mW 785 nm laser power and 100X objective.

Raman Stokes ( $100\text{ cm}^{-1}$  to  $8000\text{ cm}^{-1}$ ) of the ball milled FeOOH sample recorded with 25% and 50% 300 mW 785 nm laser power and 100X objective.

Raman anti-Stokes ( $-50 \text{ cm}^{-1}$  to  $-8000 \text{ cm}^{-1}$ ) and Stokes ( $100 \text{ cm}^{-1}$  to  $8000 \text{ cm}^{-1}$ ) of the ball milled FeOOH sample recorded with 25% and 50% 300 mW 785 nm laser power and 100X objective. The anti-Stokes emission is the source of the Stokes-spectral lines assigned to second and third order high-energy emission.

- The anti-Stokes and Stokes spectra are remarkable in that the energy ranges are higher than any prior recorded, there is a threshold laser intensity to observe the emission lines, and the first, second, and third order peaks are observed that match the rotational transitions of  $\text{H}_2(1/4)$  and not any known source.
- The Raman results provide strong confirmation of  $\text{H}_2(1/4)$  and the two-photon excitation mechanism of the rotational energy levels of  $\text{H}_2(1/4)$ .

Raman anti-Stokes ( $-50\text{ cm}^{-1}$  to  $-8000\text{ cm}^{-1}$ ) of ball milled CoOOH and ball milled non-magnetic chemical mixture KI-NH<sub>4</sub>NO<sub>3</sub> recorded with 50% of 300 mW 785 nm laser power and 100X objective. The anti-Stokes emission that was only observed on the CoOOH product with a magnetic matrix is the source of the Stokes-spectral lines assigned to second and third order high-energy emission.

Raman Stokes (4000  $\text{cm}^{-1}$  to 8000  $\text{cm}^{-1}$ ) of ball milled CoOOH recorded with 50% of 300 mW 785 nm laser power and 100X objective. The peaks match the corresponding second and third order lines of the anti-Stokes lines.

Raman anti-Stokes ( $-50 \text{ cm}^{-1}$  to  $-8000 \text{ cm}^{-1}$ ) of the Ni and tin-coated Ni foil samples run in the SunCell<sup>®</sup> and control Ni foil recorded with 50% of 300 mW 785 nm laser power and 100X objective. The anti-Stokes emission is the source of the Stokes-spectral lines assigned to second and third order high-energy emission. The results demonstrate that the reaction of  $\text{H}_2$  to  $\text{H}_2(1/4)$  is the source of SunCell<sup>®</sup> power gain.

Raman Stokes ( $3000\text{ cm}^{-1}$  to  $8000\text{ cm}^{-1}$ ) of the Ni and tin-coated Ni foil samples run in the SunCell<sup>®</sup> and control Ni foil recorded with 50% of 300 mW 785 nm laser power and 100X objective. The peaks match the corresponding second and third order lines of the anti-Stokes lines.

# Raman Spectroscopy of $H_2(1/4)$ With Application of a Magnetic Field

- Raman spectra obtained using a Horiba Jobin Yvon LabRam ARAMIS spectrometer with an 11 mW laser 785 nm laser on a Ni foil prepared by immersion in the molten gallium of a SunCell that maintained a hydrino plasma reaction for 10 minutes. A. 2500  $\text{cm}^{-1}$  to 11,000  $\text{cm}^{-1}$  region. B. 3700  $\text{cm}^{-1}$  to 5500  $\text{cm}^{-1}$  region with Ni foil magnetized with a 1 T neodymium magnet.
- $H_2(1/4)$  showed a series of SQUID-like fluxon transitions of a single rotational and spin-orbital split level as high-energy emission observed by Raman spectroscopy on magnetic  $\text{Fe}_2\text{O}_3$  and  $\text{FeOOH}$  samples.
- Ni foil samples run at a temperature above the Ni Curie temperature and then magnetized by the application of 1T magnetic flux, switched from discrete high-energy emission lines corresponding to  $H_2(1/4)$  rotational transitions slit by spin-orbital and fluxon linkage transitions to the series of fluxon transitions of a single rotational and spin-orbital split level that matches the spectra of magnetic  $\text{Fe}_2\text{O}_3$  and  $\text{FeOOH}$  samples.
- The high energy emission assignments were confirmed by elimination of the lines by an 805 nm long-pass edge filter between the sample and the detector.

(A)

(B)

# High-Energy Emission Lines (16,800-16,100 $\text{cm}^{-1}$ ) of $\text{GaOOH:H}_2(1/4):\text{H}_2\text{O}$

- Raman spectra (14,000-14,700  $\text{cm}^{-1}$ ) of 50:50 vol%  $\text{GaOOH:H}_2(1/4):\text{H}_2\text{O}$  and controls recorded using a Horiba Jobin Yvon LabRam ARAMIS with a 325 nm laser.
- $\text{GaOOH:H}_2(1/4)$  was formed by dissolving  $\text{Ga}_2\text{O}_3$  collected from a hydrido reaction run in the SunCell® in 4M aqueous KOH, allowing fibers to grow, and float to the surface where they were collected by filtration.
- $\text{GaOOH:H}_2(1/4):\text{H}_2\text{O}$  was formed by suspending  $\text{GaOOH:H}_2(1/4)$  in  $\text{H}_2\text{O}$  at 50:50 vol% .
- Based on the absence of a change in the spectrum with a 331 long-pass edge filter placed between the laser and the sample and placed between the sample and the detector, the series of peaks observed on  $\text{GaOOH:H}_2(1/4):\text{H}_2\text{O}$  was assigned to 587.8 nm laser line excitation with emission from the  $\text{H}_2(1/4) J_p'=3, J_c'=1$  double rotational transition level split by spin-orbital coupling and fluxon linkages.
- The peaks were absent in controls 4M KOH and deionized water.
- **Seventeen of the lines of the emission spectrum match members of the Diffuse Interstellar Medium (DIBs).**

# High-Energy H<sub>2</sub>(1/4) Ro-Vibrational Emission Lines (17,900-16,200 cm<sup>-1</sup>)

- 325 nm Raman spectra (12,250-14,750 cm<sup>-1</sup>) were obtained on the plasma and molten gallium exposed surfaces of a Ni foil maintained in a SunCell® during a hydrino plasma reaction for 10 minutes.
- The corresponding series of emission peaks (17,900-16,200 cm<sup>-1</sup>) observed on the plasma exposed side was assigned to 587.8 nm laser line excitation with emission from the H<sub>2</sub>(1/4) J<sub>p</sub>'=3, J<sub>c</sub>'=1,2 double rotational transition levels split by spin-orbital coupling and fluxon linkages.
- Many of the peaks matched those recorded on GaOOH:H<sub>2</sub>(1/4):H<sub>2</sub>O.
- Forty-five of the lines of the combined emission spectra match members of the Diffuse Interstellar Medium (DIBs).

# High-Energy $H_2(1/4)$ Ro-Vibrational Emission Lines (17,900-16,200 $\text{cm}^{-1}$ )

- 325 nm Raman spectra (12,250-14,750  $\text{cm}^{-1}$ ) were obtained on the plasma and molten tin exposed surfaces of a Ni foil maintained in a SunCell<sup>®</sup> during a hydrino plasma reaction for 10 minutes.
- The corresponding observed series of emission peaks (17,900-16,200  $\text{cm}^{-1}$ ) was assigned to 587.8 nm laser line excitation with emission from the  $H_2(1/4)$   $J_p'=3, J_c'=1,2$  double rotational transition levels split by spin-orbital coupling and fluxon linkages.
- The results further demonstrate that the reaction of  $H_2$  to  $H_2(1/4)$  is the source of SunCell<sup>®</sup> power gain.

# High-Energy $\text{H}_2(1/4)$ Ro-Vibrational Emission Lines ( $15,750\text{--}16,750\text{ cm}^{-1}$ )

- 442 nm Raman spectra ( $13,000\text{--}15,000\text{ cm}^{-1}$ ) were obtained on the Ni foils used to record the 325 nm Raman results.
- The corresponding series of emission peaks ( $15,750\text{--}16,750\text{ cm}^{-1}$ ) was assigned to 442 nm laser line excitation with emission from the  $\text{H}_2(1/4)$   $J_p'=3$ ,  $J_c'=1$  double rotational transition levels split by spin-orbital coupling and fluxon linkages.
- First order and second order emission peaks were observed.
- The 442 nm results confirm the excitation mechanism of the 325 nm Raman spectra.
- Ten of the lines of the 442 emission spectrum match members of the Diffuse Interstellar Medium (DIBs).

# MoWeb: Vibrating Sample Magnetometer

- Paramagnetic material responds linearly with the induced magnetism.
- The observed “S” shape is characteristic of super paramagnetic, a hybrid of ferromagnetism and para magnetism.
- It is exception that the induced magnetism peaks at 5K Oe and declines with higher applied field.

# $^1\text{H}$ MAS NMR Spectra

$^1\text{H}$  MAS NMR spectrum relative to external TMS of the KCl getter exposed to hydrino gas that shows upfield shifted matrix peak a -4.6 ppm due to the magnetism of molecular hydrino.

# ToF-SIMS Spectrum of $\text{K}_2\text{CO}_3$ -KCl (30:70 wt%) getter exposed to hydrino gas and having upfield shifted MAS NMR spectral peaks.

Multimer clusters of getter compounds with di-hydrogen as part of the structure,  $\text{M}:\text{H}_2$  ( $\text{M} = \text{KOH}$  or  $\text{K}_2\text{CO}_3$ ) such as  $\text{K}^+(\text{H}_2:\text{K}_2\text{CO}_3)_n$  and  $\text{K}^+(\text{H}_2:\text{KOH})_n$  consistent with  $\text{H}_2(1/p)$  as a complex in the structure were observed. These clusters were not observed in controls comprising the matrix exposed to  $\text{H}_2$ .

Positive ToF-SIMS,  
 $m/e = 90$  to  $100$   
region

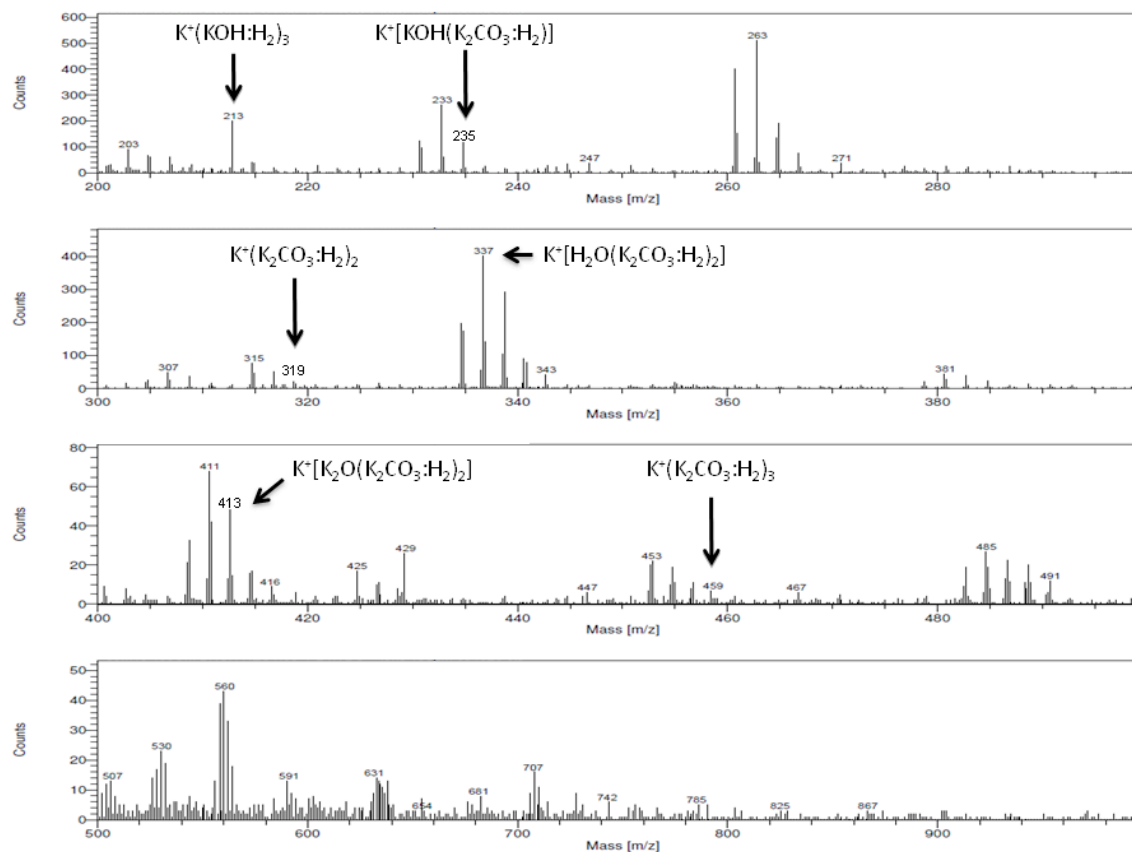

Positive ToF-SIMS,  
 $m/e = 0$  to  $200$   
region.

R. Mills, X Yu, Y. Lu, G Chu, J. He, J. Lotoski, "Catalyst induced hydrino transition (CIHT) electrochemical cell," (2012), Int. J. Energy Res., (2013), DOI: 10.1002/er.3142.

# Inorganic Hydrino Complex Behaves as an Organic Molecule in Chromatographic Analysis with an Aqueous Solution and an Organic Column Packing

- Using an Agilent Technologies 6230 TOFLC/MS and a C18 50 x 2mm 3 $\mu$ m (P/N 94641-12) column, liquid chromatography was performed on an energy dispersive X-ray spectroscopy (EDS) determined gallium (59 at%)/oxygen (38 at%)/carbon (2 at%) sample collected from a hydrino reaction run in the SunCell<sup>®</sup> and dissolved in 4M NaOH wherein the hydrino composition H<sub>2</sub>(1/4) was confirmed by XPS and EPR.
- Following the injection of 20  $\mu$ l of the liquid sample, an inorganic hydrino complex was eluted with a water + acetonitrile-water gradient.
- When using an organic column, inorganic compounds such as sodium carbonate chromatographically elute with the void volume with no retention time.
- Remarkably, when molecular hydrino complexed with sodium carbonate organic molecular behavior was observed. The complex showed a chromatographic peak at **23 minutes**.
- The **peak fragmented into inorganic ions** that identified the complex as comprising sodium carbonate.

# Gas Chromatography Controls and Hydrino Gas with Helium Carrier Gas

- The gas chromatographs were recorded with the HP 5890 Series II gas chromatograph using an Agilent molecular sieve column with helium carrier gas and a thermal conductivity detector (TCD) set at  $60^{\circ}\text{C}$  so that any  $\text{H}_2$  peak was positive. Air comprising oxygen (20%), nitrogen (80%), and trace  $\text{H}_2\text{O}$  and the following control gases from Atlantic State Specialty Gas were tested: hydrogen ultrahigh purity (UHP), methane (UHP), and hydrogen (HUP)/methane (UHP) (90/10%).
- The gas chromatographs of molecular hydrino gas evolved from heating a  $\text{GaOOH}:\text{H}_2(1/4)$  sample to  $950^{\circ}\text{C}$  that was prepared by collecting  $\text{Ga}_2\text{O}_3$  following a hydrino reaction run in the SunCell<sup>®</sup>, dissolving the solid in 4M NaOH, filtering the solution, and collecting the solid on the filter paper.
- The gas comprising hydrogen and  $\text{H}_2(1/4)$  was allowed to stand in the vessel for over 24 hours following the time of the recording of the corresponding gas chromatograph.
- The mass spectrum of gas evolved from  $\text{Ga}_2\text{O}_3$  collected from a hydrino reaction run in the SunCell<sup>®</sup> and heated to  $950^{\circ}\text{C}$  that was recorded after the recording of the corresponding gas chromatograph confirmed the presence of hydrogen and methane.

1000 Torr hydrogen showed a positive peak at 10 minutes.

1000 Torr methane showed a small positive H<sub>2</sub>O contamination peak at 17 minutes and a positive methane peak at 50.5 minutes.

1000 Torr hydrogen (90%) and methane (10%) mixture showed a positive hydrogen peak at 10 minutes and a positive methane peak at 50.2 minutes.

760 Torr air showed a very small positive H<sub>2</sub>O peak at 17.1 minutes, a positive oxygen peak at 17.6 minutes, and a positive nitrogen peak at 35.7 minutes.

Gas from heating gallium metal to 950°C showed no peaks.

# Hydrino gas evolved from $\text{Ga}_2\text{O}_3$ collected from a hydrino reaction run in the SunCell®.

The known positive hydrogen peak was observed at 10 minutes, and a novel negative peak observed at 9 minutes having positive leading and trailing edges at 8.9 minutes and 9.3 minutes, respectively, was assigned to  $\text{H}_2(1/4)$ . No known gas has a faster migration time and high thermal conductivity than  $\text{H}_2$  or He which is characteristic of and identifies hydrino since it has a much greater mean free path due to exemplary  $\text{H}_2(1/4)$  having 64 times smaller volume and 16 times smaller ballistic cross section. Methane was observed at 53.4 minutes and was also confirmed by TGA/MS.

Expanded view of negative peak assigned to H<sub>2</sub>(1/4).

The gas comprising hydrogen and  $\text{H}_2(1/4)$  was allowed to stand in the vessel for over 24 hours following the time of the recording of the gas chromatograph. The hydrogen peak was observed again at 10 minutes with a  $\text{N}_2$  contamination peak at 37.4 minutes, but the novel negative peak with shorter retention time than hydrogen was absent, consistent with the smaller size and corresponding high diffusivity of  $\text{H}_2(1/4)$  even compared to  $\text{H}_2$ .

Hydrino gas evolved from  $\text{Ga}_2\text{O}_3$  collected from a second hydrino reaction run in the SunCell®.

The known positive hydrogen peak was observed at 10 minutes, a positive unknown peak was observed at 42.4 minutes, methane was observed at 51.8 minutes, and the negative  $\text{H}_2(1/4)$  peak was observed at 8.76 minutes having positive leading and trailing edges at 8.66 minutes and 9.3 minutes, respectively.

Expanded view of negative peak assigned to  $\text{H}_2(1/4)$ .

Hydrino gas evolved from  $\text{Ga}_2\text{O}_3$  collected from a third hydrino reaction run in the SunCell®.

The known positive hydrogen peak was observed at 10 minutes, methane was observed at 51.9 minutes, and the negative  $\text{H}_2(1/4)$  peak was observed at 8.8 minutes having positive leading and trailing edges at 8.7 minutes and 9.3 minutes, respectively.

Expanded view of negative peak assigned to  $\text{H}_2(1/4)$ .

Hydrogen and methane were confirmed by mass spectroscopy.

Following standing for over 24 hours, the gas chromatograph of the gas comprising  $\text{H}_2(1/4)$  showed the hydrogen peak at 10 minutes and the methane peak at 53.7 minutes again, but the novel negative peak with shorter retention time than hydrogen was absent due to diffusion from the vessel.

# Negative, Extraordinarily Fast Hydrino Peak Replicated on a Second Matching Gas Chromatograph, Column, and Conditions

Hydrino gas was evolved from  $\text{Ga}_2\text{O}_3$  collected from a hydrino reaction run in the SunCell® and analyzed on a second matching gas chromatography system. The known positive hydrogen peak was observed at 10.8 minutes, and the negative  $\text{H}_2(1/4)$  peak was observed at 9.8 minutes having positive leading and trailing edges at 9.7 minutes and 10.2 minutes, respectively.

# Isolation and Identification of Molecular Hydrino Gas Directly from SunCell® Gas Using Liquid Argon Solvent

To remove the high masking background from hydrogen that floods the gas chromatograph, liquid argon was used as a selective solvent.

The gas chromatograph of molecular hydrino gas flowed from the SunCell®, absorbed into the liquid argon as a solvent, and then released by allowing liquid argon to vaporize upon warming to 27 °C. The H<sub>2</sub>(1/4) hydrino peak was observed at 8.05 minutes compared to hydrogen that was observed later at 12.58 minutes on the Agilent column (Agilent molecular sieve 5 Å, (50 m x 0.32, df = 30 µm) at 303 K (30 °C) using a second HP 5890 Series II gas chromatograph with a thermal conductivity detector at 85 °C and argon carrier gas at 19 PSI.

# Hydrino $\text{H}_2(1/4)$ Observed by Gas Chromatography Following Isolation by Gas Purification Using Cryogenic Chromatography and Condensation at Cryogenic Temperature

- $\text{H}_2(1/4)$  gas of an argon/ $\text{H}_2(1/4)$  mixture formed by recombination of hydrogen and oxygen on a supported noble metal catalyst in an argon atmosphere was enriched by flowing the mixture through a HayeSep® D chromatographic column cooled to a cryogenic temperature in a liquid argon.
- The argon was partially liquefied to permit the flowing molecular hydrino gas to be enriched as indicated by the dramatic increase in the ro-vibrational P branch of  $\text{H}_2(1/4)$  observed by e-beam excitation emission spectroscopy.
- The molecular hydrino gas from the chromatographic column was also liquified with trace air as it was flowed into a valved microchamber cooled to 55 K by a cryopump system).
- The liquefied gas was warmed to room temperature to achieve 1000 Torr chamber pressure and was injected on to the Agilent column with argon carrier gas. Oxygen and nitrogen were observed at 19 and 35 minutes, respectively.  $\text{H}_2(1/4)$  was observed at 6.9 minutes.

# Isolation and Identification of Molecular Hydrino Gas Directly from SunCell® Gas Using Solid Carbon Dioxide Absorbent

The gas chromatograph of molecular hydrino gas flowed from the SunCell®, absorbed into solid CO<sub>2</sub>, and then released by allowing the CO<sub>2</sub>(s) to vaporize upon warming to 27 °C. The H<sub>2</sub>(1/4) hydrino peak was observed at 9.3 minutes compared to hydrogen that was observed later at 11.1 minutes on the Agilent column (Agilent molecular sieve 5 Å, (50 m x 0.32, df = 30 µm) at 303 K (60 °C) using a second HP 5890 Series II gas chromatograph with a thermal conductivity detector at 60 °C and argon carrier gas at 19 PSI.

# Isolation and Identification of Molecular Hydrino Gas Directly from SunCell® Gas Using a Cryopump

H<sub>2</sub>(1/4) gas was collected from a SunCell® operated at a cell pressure of 10-20 Torr over 100s using a valved microchamber connected to the vacuum line and cooled to 10.5 K by a cryopump system (Helix Corp., CTI-Cryogenics Model SC compressor; TRI-Research Model T-2000D-IEEE controller; Helix Corp., CTI-Cryogenics model 22 cryodyne). The SunCell® comprised a Type 347 stainless steel (SS) cylindrical tube measuring 7.3 cm ID, 19.7 cm in height, and 0.635 cm thick with 3.17 mm thick boron nitride (99%) liner and incorporating a 0.9 kg internal mass of liquid gallium wherein the gas flow rates were 2500 sccm H<sub>2</sub>/50 sccm O<sub>2</sub>, and the ignition current was 1500 A. Argon and trace oxygen were flowed before the reaction was initiated to serve as a solvent for hydrino gas H<sub>2</sub>(1/4).

The liquefied gas was warmed to room temperature to achieve 23 Torr chamber pressure and was injected into an HP 5890 Series II gas chromatograph with a capillary column (Agilent molecular sieve 5 Å, (50 m x 0.32, df = 30 µm) at 303 K (30 °C), argon carrier gas, and a thermal conductivity detector (TCD) at 60 °C.

- H<sub>2</sub>(1/4) was observed at 10.92 minutes, oxygen was observed at 18.05 minutes, and hydrogen that co-condensed with H<sub>2</sub>(1/4) gas was observed at 12.7 minutes.
- Hydrogen condensed under pressure and temperature conditions that violate the Clausius Clapeyron equation due to the raising of the H<sub>2</sub> liquefaction temperature by co-condensation with H<sub>2</sub>(1/4).

# Isolation and Identification of Molecular Hydrino Gas Directly from SunCell® Gas Using a Cryopump Cont'd

- Hydrino atoms have a potential energy of an integer multiple of 27.2 eV matching the hydrino catalyst criterion.
- Thus, hydrino atoms serving as catalysts may react with H to form lower energy states than those of the catalysts.
- A favored reaction is the catalysis of H to H(1/17) by H(1/4) serving as the catalyst:  $H(1/4) + H \rightarrow H(1/17)$ .
- The SunCell was operated for one hour at excess power levels of over 100 kW with the intention of forming molecular hydrino states  $H_2(1/p)$  with  $p=4$  and  $p=17$ .
- The gas chromatograph of gas collected from the SunCell® by a cryopump showed a small reproducible peak at 1.95 minutes that is a candidate for  $H_2(1/17)$  in addition to the  $H_2(1/4)$  peak at 11 minutes.

# Identification of Molecular Hydrino Gas Released from Heating GaOOH and Stainless Alloys formed in the SunCell® that Had Absorbed H<sub>2</sub>(1/4) Gas

- The SunCell was operated for one hour at excess power levels of over 100 kW.
- The gallium temperature was elevated above the threshold for Ga<sub>3</sub>F, Ga<sub>3</sub>Ni, and Ga<sub>3</sub>Cr to form while the oxygen of hydrino reaction mixture was maintained elevated to form Ga<sub>2</sub>O<sub>3</sub>.
- A mixture of alloys and gallium oxide was collected from the cell, dissolved in 4 M KOH, and filtered.
- Using an Agilent 8890 gas chromatograph system with a thermal conductivity detector (TCD), gas chromatograph was performed on hydrino gas evolved by heating the non-dissolved KOH-treated alloy/Ga<sub>2</sub>O<sub>3</sub> material collected from the SunCell® to 800°C.
- The known hydrogen peak was observed at 8 minutes, a nitrogen peak was observed at 15 minutes, and a novel peak observed at 6 minutes was assigned to H<sub>2</sub>(1/4).
